Having had occasion to fill some of these unsightly gulleys, we adopted the following plan. Fig. 1 represents a very usual form of these hollows, which are to be first partly filled with stone or brush gathered from the most convenient point. If brush is used, it should be well packed and trodden down; if stone is used, the large ones should be thrown into the bottom, and the top covered with small ones. When the hollow is filled sufficiently with these materials, the ground is plowed from each side towards the center, gradually moving the earth un-

Fig. 2.—THE GULLY FILLED.

til a gentle slope is made, as at figure 2; the dotted line shows the original surface of the ground.

MORTALITY AMONG TURKEYS.—A correspondent from Fort Collins, Col., complains of great mortality among his turkeys. "They commenced dying off without anything, apparently, ailing them. They would go to roost at night, apparently in the best of health, and in the morning three or four, and sometimes eight or ten, would be lying under the roosts dead. Others would droop an hour or two, and then fall over. They had access to good water, and wheat and rye stubble, and were gaining very fast, and in superb condition. Of my flock of seventy-five, only five are now living. What was the matter?"—It is difficult, on these data, to state the exact cause, or to give a remedy. It is probable, however, that the cause of death was gorging with grain, found in the stubble, in addition to the insects which we suppose to be abundant in that

region. Without the stubble they might have escaped any harm. Our best turkey raisers feed about 4 o'clock in the P. M., to encourage the flocks to come home early, and give time for digestion before they go to roost. This regular supply prevents over-feeding, and the turkey crop is, with Eastern farmers, as sure as any other.

A Good Dog Law in Connecticut.

In Connecticut there were four deaths from hydrophobia in 1876, seven in 1877, and two already this year. Among the above were several prominent citizens. There has been paid annually, \$12,000 to \$15,000, or more, for sheep killed by dogs, while thousands of others have been maimed but not paid for. Though many parts of the State are specially adapted to raising sheep profitably, the fear of loss from dogs has nearly put an end to this industry. The above condition of things led the State Legislature, recently adjourned, to pass, with great unanimity, a stringent dog law, of which the principal provisions are the following:

Every dog kept must be registered on or before May 1st, of each year, and \$2.15 paid therefor, to the Town Clerk for each male dog, and \$6.15 for each female dog. Every dog must constantly wear around the neck a collar distinctly marked with the register number and the owner's name.—Every dog not so licensed and collared, is to be killed, and \$1 bounty is paid for the killing.—Any person keeping an unregistered dog may be fined \$7, or imprisoned 30 days, or both; and it is made the duty of Grand Jurors and all other prosecuting officers, to prosecute any violation of this act.—All damages done by dogs to sheep or lambs, or cattle, are to be paid for by the town, and collected in full from the owners of the dogs. Any person killing a registered dog, unless such killing be justifiable for the protection of life or property, is liable for the value of the dog, as established by competent evidence, and to a fine not exceeding \$7, or imprisonment not exceeding 30 days, or both.

The European Sparrow—Is It a Friend or an Enemy of the Horticulturist and Farmer?

BY DR. H. A. HAGEN, PROFESSOR AT HARVARD UNIVERSITY.

[But a few years ago, European Sparrows were hailed as the greatest boon to fruit growers, and were eagerly purchased from importers at \$4 the pair. Within the past two or three years the bird has been as positively decried, as it was before extravagantly praised. The Sparrow controversy has been especially active in Boston and vicinity, and the literature, pro and con, is already voluminous. A decision adverse to the Sparrow, given by the "Nuttall Club," an association of young ornithologists at Cambridge, Mass., has induced Doct. Hagen to enter his protest. Doct. H. is one of our highest authorities in Natural History, and is connected with the "Museum of Comparative Anatomy" (founded by Agassiz) as entomologist. He addressed his defence of the Sparrow to our first ornithologist, Prof. S. F. Baird, of the Smithsonian Institution, who forwards it to us with this remark: "It is time, I think, that something should be said in defence of the Sparrow against the numerous attacks that have been made upon it. Without pretending to form a judgment in the matter, I am anxious to see both sides represented. The leading Natural History weeklies have done little else than abuse the Sparrow, and I would like to see Doct. Hagen's protest placed on record."—We here give the article referred to.—ED.]

The decisions of the "Nuttall Club," of which a report is given in No. 18 of the "New York Country," are based upon observations contradicting in several points the older ones, which are accepted by science, in the most decided manner. It appears by the report, that the Club either had no knowledge of these earlier observations, covering a space of more than a century, and sustained by ornithologists of well known reputation, or that it

did not deem it worth while to compare its own observations with the earlier ones, which ought to have been done to fulfill the well known demands of science. The Sparrow literature is large, and opinions during the past century have considerably changed, until the final decision is most decidedly favorable to its value.

I will select only three authors, who are ornithologists, each one an authority for the economic natural history of his time, covering a space of a hundred years, and showing the gradual progress of the opinion as to the value of the Sparrow.

Mr. T. F. Bock, in 1784, considered the Sparrow simply as a nuisance, so injurious and obnoxious, he demanded that the Legislature should be applied to for its destruction; this was carried out several times with such a pernicious effect, that the Sparrow had to be introduced again. It is not necessary to give Mr. Bock's decisions, as they are exactly identical—the carnivorous and murderous habits excepted—with those of the Nuttall Club in 1878.

Mr. F. M. Bechstein, in 1795, says: "The food of the Sparrow, insects and grains, indicates him to be beneficial as well as injurious. In spring, he visits all fruit trees, collects caterpillars from the leaves and flowers, and kills an exceedingly large number of May-beetles to feed his young. In summer, he lives on the seeds of lettuce and of spinach, on young peas, cherries, grapes, and berries. In the fall, he goes into the grainfield and eats a large quantity of ripening or ripe grain. The greatest benefit he confers is in the destruction of innumerable noxious insects, May-beetles, pea-grubs, caterpillars, and grasshoppers, to feed his young." The Sparrow is from this not so injurious as he was declared to be in former times, and upon the whole is certainly more beneficial than harmful. I know towns where Sparrows were killed as injurious, but the fruit trees there never had fruit, though other towns in the neighborhood had plenty of it. The cause was, that the caterpillars were not killed by the Sparrows. Through loss came wisdom; the Sparrows were again introduced, and it was found more profitable to protect the fruit trees and vines against their depredation by simple artificial means.

Dr. C. W. L. Gloger, in 1858, says: "The formerly much-abused Sparrow is often an impudent fellow, but he eats insects as long as they are to be found. With some predilection, he collects leaflice from the buds of shrubs, and trees, and feeds his young with caterpillars. Certainly the Sparrow merits well the few berries and grapes which he steals, as he protects so many other fruits, which he leaves untouched. In former times people were shortsighted enough to hunt and to kill the Sparrow; now opinion has changed. All intelligent horticulturists especially, will never persecute the Sparrow." Among the large number of books on horticulture, there is not one, which even excuses, much less commends, its destruction. If the Sparrows were injurious, they would be much more so for horticulturists than for farmers. The stomach of the Sparrow, in fall or winter, is rounded with seeds of weeds, which is certainly more than an equivalent for the grain stolen in summer.

These opinions are based upon observations made through a century, and supported by authors of acknowledged reputation, while the decisions of the "Nuttall Club" are given after only the observations of a few years. I would only object to a few observations given in the report, the rest being sufficiently answered by the above extracts.

The report states "the Sparrows to be carnivorous birds, eagerly destroying and devouring eggs, and newly-hatched young of other birds." It is well known to every naturalist, what science understands by the term "carnivorous birds," and it is well known that Sparrows do not belong to them. This term, as applied to the Sparrow, is decidedly out of place in the report of an Ornithological Club. The other part of the quotation reminds me of a quibble a century old. It was said that "the Sparrow invades the nests of pigeons, to eat open the crop of the young ones, and to feed upon the grain contained in them—when he needs it." Of course it was understood that he never needed it.

The report says further, "The decided preference

for fruits and leaf-buds (the last observation is an original one of the "Nuttall Club"), renders them decidedly a pest to horticulturists." As this statement, if true, would be alarming for horticulturists, I should be very glad if the above quoted contradictory observations of Beechstein and Gloger would find a place in some prominent paper or magazine devoted to the interests of horticulturists. But I can give them some farther consolation. It is, perhaps, not commonly known to what an extent the horticulturists here find it profitable to depend upon German horticulturists. In 1867, wishing to send home a set of flower seeds, I went to the most prominent dealers, stated my purpose, and got the answer: "We import all our seeds from Germany." In 1874, I was asked by a friend to send the seeds of the American native Pine-trees. After going around in Boston, without success, I wrote to New York, Philadelphia, and St. Louis, and had from all the same answer. Now, when American dealers find it profitable to import seeds from Germany, and German dealers find it profitable to export them, it is rather obvious that the Sparrows, so exceedingly common in Germany nursery gardens, can not be a pest there, and consequently will not be a pest here. A book commending the persecution of Sparrows would at this day be considered by intelligent German horticulturists as a curiosity. The argument suggested in the report of the "Club," that the help of the Sparrows is not needed for the suppression of the Canker-worm, because various effective devices exist for the protection of fruit and shade-trees, decidedly loses its value, when summer after summer we have seen those devices applied with care, and in spite of these the foliage was destroyed—except where Sparrows were present in sufficient number to check it. Prominence has always been given to the alleged fact, that the Sparrows drive off indigenous birds. According to my personal observation in Cambridge, and other suburbs of Boston, this is not true. When I arrived here in 1867 I was surprised by the scarcity of birds in such a large number of beautiful gardens and splendid grounds. The following spring, I was able to understand why birds were so rare here, as I saw and heard, morning and afternoon, around and very near to the Museum, and elsewhere, the shooting of every kind of bird. I saw boys plundering the nests of the most valuable insect-eaters, Robins not excepted, and I also saw target-shooting in the open field; the target fastened to large trees, upon which were birds-nests. During recent years the protection of Sparrows has surely saved the native birds, and I have never seen in Cambridge more native birds, and never heard more beautiful song birds than in the summer of 1877. Concerning the diminished number of native birds in the Smithsonian grounds in Washington, recorded in the report of the Club, I am assured that one of the foremost American Ornithologists denies it to be the fact. After all, it should not be forgotten that by the rapid increase of the cities (Cambridge has more than twice as many inhabitants now as it had in 1867), and with the incessant disappearance of trees and shrubs, some kinds of birds may prefer to go to more secluded places.

The argument that Sparrows drive other birds out of the bird-boxes, is a rather funny one, when it will be remembered that all those bird-boxes were placed only for the Sparrow. I think every bird will fight for its home, nevertheless I observed, in 1877, Sparrows driven out of the box which they had used the year before by Swallows, which raised their young safely among a dozen of boxes near by used by Sparrows. In a box in the garden at the corner of Broadway and Harvard St., a pair of Sparrows and one of Swallows settled last year together. The box had only one entrance, through which both had to pass, and as there were two glass windows in the box, both nests could be observed, and the young of both were safely raised. If, as it seems to be the case, that native birds prefer now to breed in bird-boxes, which they did not and could not do here in former years, it would be simply reasonable to place more boxes everywhere, and as is done in Europe, different sizes for different kinds of birds.

Nobody has ever contended that the Sparrow is a beauty or a charming singer. Indeed, he is only

an indefatigable business man, minding first his own affairs, as is not uncommon among business men. But he is admirably adapted for his business—which is to destroy insects; he is very enduring, staying through the winter, when few other insect-eating birds are here; he begins to breed much earlier, and breeds much oftener, than other birds, and is, therefore, more able to give an effective help in the destruction of insects and weeds. But it is true that he should be supported, as Mr. Allen remarks judiciously in the report, through enforcing, by statutory enactments, the protection of the fruit and shade trees by all available means.

As no naturalist would pretend, that a bird, by importation into a foreign, but similar, climate, could entirely change its character in a few years, the Sparrow question will probably here go through the same, though briefer, stages of opinion as in Europe. I consider the Sparrow to be a valuable addition to the native birds, and most certainly beneficial for both horticulturists and farmers.

A Wisconsin Barn.

"E. T. C., Dane Co., Wis., sends a plan of a style of barn which is common in his neighborhood, and is found satisfactory to the farmers there. It is 60 feet long, 32 feet wide, with 18 feet posts. It has four bents, with a granary at one end, and a

Fig. 1.—PLAN OF BASEMENT.

stone basement, 8 feet high, under the whole building, with sliding windows in the basement. Figure 1 shows the plan of the basement. There are three cattle stalls, A, A, A, each 14x32 feet, and having 10 stanchions; at B is the horse stable, 18x32 feet,

Fig. 2.—PLAN OF SECOND FLOOR.

for 6 horses; at C, C, C, are 3 hay shoots, 2 feet square, passing from the manger to the floor over the granary; at D is a box, 3 feet square, with spout from the oat-bin in the granary above. Figure 2 shows the plan of the second

floor; at A, A, are 2 hay bays; at B is the rive-way; at C, C, C, are the hay shoots; at D is the stair-way; at E, E, are spaces on each side of the drive-way for throwing hay down to the cattle; at F is the granary. Figure 3 shows the plan of the hay-bay over the granary; C, C, C, being the tops of the hay shoots. All the doors in the building are hung upon rollers. The granary is made of matched boards, and the walls are lined in the same way between the studding and the siding. The basement is floored with plank, with a 2-inch drop behind the horses, and a 4-inch drop behind the cows.

Fig. 3.—PLAN OF HAY-BAY.

The granary is made of matched boards, and the walls are lined in the same way between the studding and the siding. The basement is floored with plank, with a 2-inch drop behind the horses, and a 4-inch drop behind the cows.

HEALTH OF CATTLE.—Here and there we hear of cases of lung-fever, "pleuro-pneumonia," among dairy cows. It is wise to use every precaution to avoid this disease. That it seems to originate in dairies in sporadic cases, would go to prove that,

like cholera and other general diseases, it is not "in the air," as is frequently supposed, but that it is caused by some conditions, which arise from the state of the stables, or the animals themselves. Damp, foul air, uncertain and changeful temperature, and the breathing of fetid emanations from filthy stables and manure heaps, all tend to poison the blood, and this is a true blood disease, as may be proved from the fact that it can be spread by inoculation. To prevent disease by observing every sanitary precaution, is always possible, and in case of this dreaded disease, we have little fear of its appearance if these precautions are generally observed. Once started on its course, however, there is no doubt of its contagious character.

Broad Tires to Wheels.

The condition of the roads the past winter, has done more to commend broad-tired wheels, than all the arguments that have ever been uttered. The soft roads have been so cut up with the 1½-inch wagon-tires, and these have sunk so deeply in the mud that, in some places, travel has been impossible for weeks at a time. Those who have been thus mud-bound, are now convinced that it might have been better for them had the tires of their wagons been 3 or 4 inches wide; but they are still in doubt about the ease of draft of these broad wheels. Now, it should be evident that a broad wheel, that will not sink into the ground, is of much easier draft than a narrow one that cuts in two or three inches. The difference in draft of a narrow and a broad wheel upon the hardest, smoothest road is inappreciable, and it is a matter of doubt if it is in favor of the one or the other. Theoretically, there may be a difference, to a small extent, in favor of the narrow tire, but as our roads are far from being hard or smooth, the difference of draft will be decidedly in favor of the broad tire. A load of manure can be drawn across plowed ground in a broad-tired wagon, by a team that could not move it in one with narrow tires, and the softer the ground, the more apparent will be the difference in favor of the broad wheels. It is to be hoped that the manufacturers of wagons will make the experiment of offering wheels with broad tires; we believe they would soon become very popular.

THE LIGHT BRAHMAS.—In a pretty large experience with fowl raising, for the last thirty years, we have tried many sorts, new and old, and have settled upon the Light Brahma as the best fowl for villagers and farmers. They are a long time in coming to maturity, but there is no difficulty in getting nice broilers from them, in July and August, or in getting eggs from the early pullets in the fall, and that is about all that can be done with the earlier varieties. Well fed pullets, beginning to lay in November, in warm quarters, will give an abundance of eggs through the winter, when they bring the best prices. They are the largest breed with which we are acquainted, adult cocks sometimes weighing 13 to 16 lbs., and hens 10 to 12 lbs. The flesh is of good quality, and when one comes to the table, there is enough to go round and some to spare. They are the most popular of all varieties, tested by the demand for breeding fowls and eggs. *

VALUE OF JERSEYS.—A public sale of a number of imported Jersey cows, in the City of New York, at an average of over \$400 each, shows that this class of stock is not deteriorating in value. An examination of the cows sold, satisfies us that a lot of equal quality could be picked up in almost any county, where there is a fair sprinkling of Jerseys, at a less price than \$400 each. These, however, were imported, and it seems to be true, now as ever, "that a prophet is not without honor save in his own country, etc." There are Jerseys now in America, and scores, if not hundreds of them, that are better than any we see imported, and no other milking stock is so rapidly taking hold of the farmer's fancy as grade Jerseys, especially for butter dairies. The greatest value of a pure breed is in its use for crossing, and the American farmers are fast finding out that the grade Jersey (or Alderney, as it is often wrongly called) is a very valuable cow.

Hints and Helps for Farmers.

BY L. D. SNOOK, YATES CO., N. Y.

OPEN DITCHES.—Intermittent, or occasionally flowing streams cannot be carried off by under-

Fig. 1.—USUAL FORM OF DITCH.

drains, on account of the large quantity of water brought down by them at certain seasons. Open ditches are, therefore, necessary to conduct away the water of these courses. Generally, these open

Fig. 2.—IMPROVED FORM OF DITCH.

ditches are a nuisance, because of their improper shape. The usual form is that of a hollow, *B*, fig. 1, with ridged banks, *E*, *E*, by which the ground is made useless when the stream is dry. In the form

Fig. 3.—PORTABLE FEEDING COOP FOR CHICKS.

shown at figure 2, there will be no obstruction to the passage of wagons or mowing machines, the grass in them can be mowed, and the sides and bottom being turfed over, there will be no washing.

A PORTABLE FEEDING COOP.—A coop in which

Fig. 4.—REVERSIBLE FEEDING TROUGH.

young chicks, that are permitted to range with the large fowls, may be fed without interference by the others, may be made as shown at figure 3. Common laths are sawn into proper lengths and nailed to a frame, three inches space being left for the chicks to go in and out. On one side the laths are cut off six inches from the ground, and a strip, *A*, 3 inches wide, is secured so as to be raised as the chicks grow larger, to permit them to pass under it. If made 10 feet long and 5 feet wide, it will accommodate 200 chicks. The frames for the sides and ends may be attached to each other by pins, or hooks and staples, and when not in use, they may be taken apart and packed away, until again required.

A FEEDING TROUGH.—A device for keeping feed-troughs free from dirt, rain, or snow, is shown at figure 4. Supports are attached to the trough, and extend above it, as at *E*, *E*, *H*, *H*. When the trough is not in use, it may be tilted over so that it will be kept free from water, or rubbish, and always be in a proper condition whenever needed for use.

DIBBLES FOR POTATO PLANTING.—When plant-

ing potatoes in rows or hills, the holes for the sets may be made very easily by means of the dibbles shown at figures 5 and 6. The first is made of a piece of hard-wood, $3\frac{1}{2}$ feet long and 2 inches thick, bluntly sharpened at one end. Pins, *A*, *A*, 10 inches long, are inserted near each end, one intended for a handle, the other to be pressed with the foot into the soil, by which the hole is made. The second is similar, excepting that a piece of iron is screwed to the wood for a step, on which to place the foot. By changing the place of the lower pin, or the step, the depth of planting may be regulated.

A CONVENIENT FEED OR GRAIN-BIN.—A feed or grain-bin, made as shown at figure 7, will be found very useful; it is divided into three compartments, and the shelf above will be a convenient place for measures or scoops. It will tend greatly to save feed if the box is provided with lock and key.

A USEFUL CORN-MARKER.—A corn-marker, which will adapt itself to any uneven and stony surface, may be made as follows: A bed piece, *R*, fig. 8, five inches square and 10 feet long, is provided. The marker-holders, *P*, *P*, four feet long and four inches square, are attached to the bed-piece by wooden pins 2 inches thick, *A*, *A*. The markers, *E*, *E*, are 10 inches long and 3×4 inches thick, and are fastened to the holders, *P*, *P*, by 2-inch holes near the ends. The markers are beveled at the bottom, to facilitate their passage over obstructions and make a more distinct mark. At *B*, *B*, are up right sticks, 3 feet long, by which the marker is guided in a straight line by the driver. At the ends of rows, the marker is lifted around by the rear handles.

HITCHING POSTS AND RINGS.—A double hitching post is shown at figure 9. It is made of two posts set in the ground and joined together by a cross-piece, mortised into them. This makes the posts

very firm, and not easily loosened or torn out of the ground. Different forms of single posts are shown at figure 10. These require no description. Rings, which may be fastened into posts or barn timbers, are shown at figure 11. One of these is made to screw into the timber; the other is fastened by a staple having notches in it, to render the hold secure.

Improvement of Corn

This being the month for planting corn over a large portion of the Northern States, some remarks about the means of improving this grain are timely. No crop that we grow has such promising possibilities as this, none is grown with less care as to its improvement. The general yield over the United States, is from 25 to 45 bushels per acre. At the

Figs. 5 & 6. DIBBLES.

rate of 100 ears to a bushel of shelled corn, this is from one to two ears to two square yards, or only about one ear to a hill under ordinary methods of cultivation. Generally three, and sometimes two, stalks are left in each hill. There are then a large number of barren plants produced. If each stalk bore one good ear, the yield would be from 50 to 150 bushels of grain to the acre. If we could produce three or four ears to one stalk, and leave but one stalk to a hill, with hills $3\frac{1}{2}$ feet apart (3,555 hills to the acre), we should gather from 100 to 140 bushels of grain per acre. If we could grow of the common northern field-corn, three ears to a hill,

that is, one ear to every stalk, with hills 3 feet apart, we should gather 145 bushels per acre. The advantage and profit from such cultivation is ap-

Fig. 7.—BIN FOR GRAIN OR FEED.

parent. The question is, how can we produce such a yield as this? It is well worth the effort to try to do it. Vegetables and animals reproduce their kind under somewhat similar laws. Like produces like in both cases. There are shy bearers in both plants

Fig. 8.—A CORN-MARKER.

and animals, but we quickly weed out of our flocks and herds the non-productive portion. If we could do the same with our corn-plants, and prevent the barren stalks from shedding their pollen upon the productive ones, we should apply the same rule which stock-breeders enforce in their yards and pens. We might go further than this, and choose

Fig. 9.—DOUBLE HITCHING POSTS.

seed from the most prolific stalks of a previous year, selected in the field; plant these in highly fertilized soil; cultivate the crop perfectly; remove the tassel from each stalk that has no ear, before the pollen is shed; and see that every ear that shows the silk is fertilized with pollen from a pro-

Fig. 10.—POSTS.

Fig. 11.—RINGS.

ductive plant. If this be carefully done for several years in succession, there can be no doubt that the effect upon the production of the crop and the value of the seed, would be highly beneficial.

The Catalpa and Its Uses.

As indicated in an article by Prof. C. S. Sargent, on p. 142, last month, the Catalpa is likely to receive much more attention at the hands of tree-planters than heretofore. One would suppose that a tree so widely planted for ornament would be generally known, yet there is scarcely any tree that

Boys often amuse themselves with the pods as substitutes for cigars, the cottony wings to the seeds giving an abundant, and probably innocent smoke. As an ornamental tree, the Catalpa, with many merits, has some faults. As already mentioned, its naked branches are unsightly, and the leaves are among the latest to appear, while they drop with the very first frosts. Its bark, when wounded or cut in the spring, is said to emit a very offensive

odor. The honey collected from its flowers is said to be poisonous, though we have seen no direct evidence upon this point. The name, *Catalpa*, is supposed to be derived from the Indians; it was originally described by Walter as *C. bignonioides*, from the resemblance of its flowers to those of the *Bignonia* or Trumpet-creepers; later botanists have called it *C. cordifolia* and *C. syriacaefolia*, but these, according to the rules, should give place to the older name. It belongs to the Bignonia Family. Our principal reason for briefly describing the Catalpa, is on account of its economic importance. In most works on trees, its timber is briefly mentioned as "lasting," though Mr. Arthur Bryant in his work gives more importance to this quality, stating that he is assured that posts "have stood for 40 years without the appearance of decay," and advises its cultivation "to a limited extent." Probably the earliest advocate of the Catalpa was General Harrison (afterwards President), who, in an agricultural address at Carthage, O., in 1825, advised farmers to cultivate it on account of its great durability for posts, etc.

especially as to durability when exposed to the weather, or in contact with the earth. As to climate, Mr. Foster thinks that the common kind can not be depended upon north of St. Louis, while the variety just mentioned has endured the severest winters of Iowa and Illinois without the least injury. That a variety in the color of the flowers, leaves, or fruit of a plant, is often accompanied by a difference in hardiness, and that some varieties are more hardy

THE CATALPA.—(*Catalpa bignonioides*.)

we are more frequently asked to name from specimens sent, than this. It is essentially a southern and south-western species, finding its northern limit in Southern Illinois and Indiana, but cultivated much farther northward. In exposed situations in northern localities, the tree is not seen at its best; the head is often very irregular from injury in severe winters, or the breaking of the branches by violent storms, and when naked is anything but an elegant object. When the abundant leaves appear, these deformities are hidden, and the whole aspect is changed. The long-petioled leaves, either opposite, or three in a whorl, are large, heart-shaped, downy on the under side, and of a peculiar shade of green. The flowers appear in June and July in large open panicles, often a foot long, and are produced in such profusion that a specimen in full-bloom is a most pleasing sight. The individual flowers are about an inch long, elongated bell-shaped, with a wavy 5-lobed border, and somewhat two-lipped; they are white, and generally tinged with violet, and spotted within with yellow and purple dots. The flowers are succeeded by long, slender, cylindrical pods, often a foot, or more, long, which hang until spring, and are so conspicuous, especially after the leaves have fallen, that in some localities the tree is known as the "Indian Bean." The pod is divided lengthwise by a partition, forming two cells, which contain numerous very flat seeds, having on each side a wing, which is much cut, and appears like a fringe.

He, when Governor of what was then the North West Territory, found Catalpa pickets in the old French stockade at Vincennes, which were yet sound, though they must have been in place for a century or more. Later, Doctor Warder and others have given testimony as to its value. Mr. E. E. Barney, of Dayton, Ohio, has, as mentioned last month, done excellent service in collecting the scattered testimony as to the value of the timber of the Catalpa, adding to it important notes of his own, and presenting the whole in a pamphlet. Mr. Barney calls attention to the fact, first pointed out by Doct. Haines, of Dayton, that there are two varieties of the Catalpa; one blooms two weeks earlier than the other, has larger flowers, which are nearly pure white, with larger, longer, and fewer seed pods. Mr. Snel Foster, a well known horticulturist of Muscatine, Iowa, has also noticed this difference, and found the early-flowering form to endure a winter which killed the ordinary kind. He proposes to call this form "*the hardy*," and the later blooming "*the common*" Catalpa. Those who contemplate tree-planting will do well to procure the pamphlet referred to (which Mr. Barney generously supplies for two 5c. stamps), as we can here only briefly sum up the evidence there presented. The valuable qualities of the tree are: ease of propagation; adaptability to various soils; rapid growth; freedom, so far as known, from the attacks of insects, and the great value of its timber,

THE SLENDER-LEAVED LILY.—(See next page.)

than the type, is well known to cultivators, and is by no means peculiar to the Catalpa. The seeds are sown in spring in nursery rows, thinned to about a foot, and transplanted when one or two years old, as may be most convenient. In the plantation they are set four feet apart each way; close planting is necessary to insure a straight, clean trunk. In 12 years, each alternate row may be cut out for telegraph poles or fence-posts, and in about 12 years more the remaining trees, in good soil, will make six railroad ties each. Mr. Barney estimates that at the present prices, a plantation of Catalpa will make a return of \$25 per acre for each year of the whole time that the trees occupy the ground. Those who have only seen isolated and scraggy specimens, can have little idea of the Catalpa as a forest tree; in favorable localities it has reached a diameter of three and even four feet, with a clean trunk of 50 feet, without a branch. The trunk of this tree is preferred in the south-west for making dug-out canoes, as they neither crack nor decay. The great durability of the timber seems to be well established, and several instances are cited in which posts set in the ground, or logs laying upon it, have been exposed from 70 to 100 years without perceptible decay. The great demand for the timber will be for railroad ties; for this use it should resist the crushing effect of great weight, as well as decay, and should also be able to hold the spikes firmly; so far as tried, the Catalpa ties have proved, when

tested side by side with ties of oak, perfectly satisfactory in these respects. One great advantage of the Catalpa over most other woods, is the inappreciable amount of sap-wood, or "sap," as the immature, recently formed outer layers of wood are popularly called. This, even in cedar and other trees, the heart-wood of which is durable, decays rapidly, but even small stakes of the Catalpa suffer no appreciable loss from this cause. Besides durability, Catalpa-wood possess beauty to a remarkable degree; its general color is a warm buff, the "silver grain" being straw-colored; it takes a fine polish, and is well suited to interior finishing and cabinet work. Mr. Barney, who is known at the West as "the Veteran Car-Builder," sends us specimens of the wood, cut in different directions, with one surface polished; one of these is from the lower end of a bar-post that is known to have been in the ground for 75 years, and though stained a little darker, is quite as sound as the others from trees cut last year. All present a beautiful polish.

One Grape Vine.

SECOND ARTICLE.

In heading our article last month, "One Grape Vine," we did not intend to imply that but one

Fig. 1.—VINE AS RECEIVED.

vine should be planted. The idea we had in view was, that whoever would plant and watch the growth of one vine, would understand about one other vine—one dozen, one hundred, or more vines. Much mystery has been thrown about the culture of the grape, by those who, not finding the old names given to the parts, sufficiently learned, have

Fig. 2.—A YOUNG SHOOT.

introduced new names for very common things. Then again the jobbing gardeners who go about, and who, unfortunately, are employed in cities and villages, put on wonderful airs. If called to treat

a vine, it is sure to have been treated badly before, and only their skill can save it, and they haek away at it, while the owner pays the bill. Now there is nothing simpler than the manner of growth of "One Grape Vine," and as one vine grows, so do all the rest. There is nothing about it that the farmer or villager, or that the boys or the girls of the villager or farmer can not understand if they will. There is no mystery about the management of a vine. One only need to know its way of growing, which can be learned from "One Grape Vine," as well as from one hundred. To go back to last month, and for convenience we re-produce figure 1, here, which shows the vine as it will be received from the nursery and planted. As it comes, it will be a dead-looking stick, with three or four prominent swellings, or buds, and a root at one end. Planted, as directed last month, these buds will start to grow, and as we then advised only one, and this one the most promising of these, should be allowed to grow. This will push out a green, and at first very tender shoot, which should be handled carefully, and be kept tied up to a stake. Now what have you in this Shoot, or Stem? Watch it as it develops and see! As the shoot grows you have a Leaf, opposite that a Tendril, to help hold up the shoot; then several inches of stem, and on the other side from the first, another leaf, with a tendril against it, and so on, as long as the shoot grows. The whole shoot is made up of, one after another, a length of stem, three to six inches or so, and a swelling, at which appears on one side a leaf, and on the other side a tendril, as in figure 2. [By some oversight, the tendril opposite the lower leaf has been omitted, it should be there.] This point where these sections of stem join, and at which leaf and tendril are attached, is a Node, the space between the nodes, an Internode, though it is popularly called a "joint." Should the vine happen to be a very strong one—and this will be seen on all fruiting vines, there will be the leaf, and, instead of the tendril, a bunch of flowers, to be followed by a cluster of grapes, as in figure 3. The tendril is then a part of the vine with a double use. It may serve to hold the vine in place, or it may bear fruit. We will not, just now, consider the fruit, as we wish to get a strong vine, fit to bear fruit next year. The angle between the leaf and the stem is called the Axil; in the axil of the leaf, as the shoot grows, will be usually found two buds, as seen in figure 3. If the vine is in vigorous growth, one of these buds will push and form a side shoot. This shoot is generally called a Lateral, though other names have been given to it, but lateral is descriptive, and easily remembered. Now with the young vine planted this spring, we wish to get as strong a shoot as possible, and we do not wish any side-shoots, or laterals. If any of these push, as they will be likely to do, so soon as they show a second leaf, pinch that off, leaving but one leaf on the lateral. The bud in the axil of that leaf upon the lateral may push out a shoot after a while; if it does, when the shoot from that has two leaves, pinch out the upper one. When we say "pinch," we mean, use the thumb and finger-nail, which will be all the tender growth requires. The young vine, started from one bud, requires just this attention: The shoot should be kept tied up to a stake—for when young, it is easily broken by the wind, or by accident, and if it shows a tendency to push laterals, these should be pinched off to one leaf as above described. Now look at this vine. It has all that any vine has. Watch its growth, now, while young, for all its future growth will simply be a repetition of this. What have you in your vine? You have a root—look out for that, for it is a very important part of the vine; then you have a piece of old last year's wood, from which—if you have followed

our advice, you will let just one green stem or shoot grow. It is most convenient to call the stem of the vine, while green and growing, a Shoot, but when it has ceased to grow, and it is no longer green, but has ripened and become brown and hard, it is then a Cane. What is that shoot? It is made up of Nodes, marked by a swelling, and separated by a few inches of stem; at each Node is on one side a Leaf, and on the other side a Tendril. At the Axil of the leaf, you have two Buds, one of which grows and forms a Lateral, which you must pinch back to one leaf, and if another growth starts, pinch that back, and so on. Well, you have now, in this

Fig. 3.—A NODE OF A VINE WITH ITS PARTS.

vine, all that any vine has, save that in older and stronger plants, and what you may have next year in your vine—instead of bare tendrils, you may have clusters of flowers, followed by clusters of fruit. Your old last year's stem, which you planted, is a cane. Your shoot, that grows from it, will ripen by and by into a cane. No matter how large the vine, no matter how it has been trained—or what is worse, not trained at all, these are all the parts with which you have to do. There is no mystery about them—all so perfectly simple that any intelligent youth can understand it. When this manner of the growth of the vine is once understood, all further treatment becomes perfectly plain.

The Slender-leaved Lily.

A collection of the different species of Lily presents a wonderful variety not only in the color and form of the flowers, but in the character of the foliage, and in the size of the plant. From the rare Giant Lily (*Lilium giganteum*), which lifts its flowers 8 and 10 feet above the ground, down to the Slender-leaved Lily (*L. tenuifolium*), which contents itself with as many inches, there is a wide interval, which is in good part filled by other species of varying stature. There are other lilies of as low growth as this slender-leaved one, but none so delicate in all its parts. This has a bulb about the size of a walnut; its stems, from 8 to 15 inches high, bear on the lower part scattered leaves, which are so narrow that they appear more like those of a grass than a lily; the upper part of the stem is nearly leafless. The flowers are one to six, nodding, and of the size and shape shown in the engraving (on p. 181); they are of the deepest scarlet, without any spots, and have a shining surface: the pollen is of a brick-red color. In none of the accounts we have seen of this species, do we find any reference to its odor, which is quite as distinct as any others of its characters; it has not the oppressive sweetness of the Gold-banded Lily (*L. auratum*), but has a spring-like freshness most enjoyable. The drawing for the engraving was made from a forced specimen, which, when but one of its three flowers was open, delightfully perfumed a large room. This species is a native of Siberia, and though it has been in cultivation for over 50 years, is still a rare plant. It

is perfectly hardy, so far as cold is concerned, but it can not endure a moist soil, and unless a specially well-drained bed can be given it, the French cultivators advise to cultivate it altogether in pots. It is altogether too fine a plant to be scarce, and we hope our cultivators will take pains to multiply it.

A Wire Trellis for Peas.

The sticking of peas is a job which gardeners would gladly avoid, as it is often difficult to secure suitable brush, and the time occupied in collecting brush and setting it is no small item. A few years ago, we figured a pea-hurdle, such as is in use in England, but this is rather costly, and takes up too much room when not in use. Mr. Z. Mills, Jr., sends an account of his method of using wire to support his pea-vines; he has employed this for several years, and finds it greatly superior to brush. The peas are sown in double rows, six inches apart, care being observed to have the rows true. A post six inches in diameter, either round or half round, is set at each end of the row; it is placed three feet in the ground, and is as high as the vines require; the earth should be pounded firmly around the posts to prevent sagging. The wire used is galvanized iron, No. 13, which measures 150 feet to the

PORTION OF PEA-TRELLIS.

pound. When the peas are tall enough to need support, the wire is attached to a post, about six inches from the ground, carried to and passed around the post at the other end of the row, and back to the starting point; here it may be made fast and cut off, but Mr. M. prefers to take two or three turns around the post, and leave the coil hanging there until another stretch of wire is needed. When the vines grow 8 or 10 inches above the first wire, a second wire is stretched in the same manner as the first, and so on until the vines cease growing. Plasterer's laths, or other strips, or bean poles, are put every 15 feet in the row as stakes to support the wires, if they sag with the weight of the vines; the stakes have notches cut to receive the wires, or these may be tied with a cord or a short piece of wire. If the rows are over 300 feet long, another post should be set midway of the row to relieve those at the end of too great a weight. When the crop is gathered, the wire is removed and wound up on a reel, and the posts stored in a dry place, ready for another season. Mr. M. trains Lima and other pole-beans in the same manner, using for these a single wire, instead of passing it on both sides of the posts, as for peas. He is sure that he can get a larger crop from beans trained on wires than from poles, but at first some care is required to train the vines, and get them properly started.

THE POTATO-BEETLE.—The experience of last season has shown how easily the potato-beetle may be vanquished. Notwithstanding this pest, potatoes are plentiful in New York markets, at \$1.50 a barrel, and farmers seem to think that these prices are better than those for most of their products. The fight with the beetle, to be successful, must be swift, short, and sharp. No other remedy is so certain as Paris Green for the larvæ, and hand-picking for the first crop of the beetles. Hand-picking early in the season, prevents the deposition of thousands of eggs, and every egg destroyed, diminishes the late crop by hundreds or thousands. If farmers would only work for one year, and destroy the beetles as long as one is to be seen, sparing none of the late crop, there would be an end of them, practically, for ever afterwards. To spare the latest brood, is to save seed for the next season.

THE HOUSEHOLD.

Home Topics.

BY FAITH ROCHESTER.

How to do a Washing.

Washing-machines are usually accompanied with printed directions for their use, but in more than half of the families throughout the country, no machine is used. The old-fashioned washboard is the main reliance. Perhaps washing does not come under the head of "skilled labor;" it is generally supposed that any one who has strong arms and back can do this work; but certainly something more than mere strength is required to do a washing well. There is a great difference in washings, as I can see in comparing my present task with ten years ago. I not only have more pieces in the wash now, but the majority of them are much harder to cleanse: this is because there are children in the family, who play out-doors in all kinds of weather. Knowing this, I am not likely to be deceived by any advertisements of machines, or soaps, or washing-fluids, which promise to do "the family washing" in an hour or two without any hard rubbing. It may all be true about some washings, but not about mine.

Many advise that the white clothes be always put in soak over-night before washing. I have not found enough help in this to pay for the trouble. I almost always use some kind of washing-fluid, or chemical soap, especially in summer, when most white clothes are used. In winter, a free use of flannels, which are easily washed, makes the work lighter. Clothes that are much soiled should not have hot water poured upon them, or be put into clear hot water, which "sets" the dirt. A hot soap-suds does not have the same effect. Yet I should prefer to wash stained articles in moderately warm suds, before putting them into hot suds. Many fruit stains are removed by pouring boiling water through the spots, but other stains cannot bear this treatment. Make, then, a good strong suds, as hot as the hand can bear. Add washing-fluid if you can, unless you have some kind of "electric" or "detergent" soap. Put in pieces to the amount of three or four or five shirts, according to the size of the tub, and amount of water. Of course, we wash first the finest, or least soiled articles. Let them soak in the strong suds a little, from five to fifteen or twenty minutes. Keep plenty of hot water in the boiler, and, to this end, fill it up whenever we take any out, keeping it somewhere near half full. If we use hard soap, it is best to shave up two-thirds of a bar, (or less if the washing is small), and dissolve it in a quart or more of hot water, upon the stove. Make the suds of this. With a good suds, and with a short soaking, the shirts, pillow-cases, fine shirts, and the under-garments of cleanly people, ought not to need much rubbing. After the first lot of pieces has been washed, wrung out, and dropped into the basket, put another lot in, adding more of the dissolved soap, or more hot water if needed. Some of the suds from the tub may be taken out first, in which to soak the especially soiled garments. When the suds in the tub becomes considerably dirty, prepare a clean suds, and in this begin with the white table-cloths, napkins, and dish-towels, if it is desired to keep these separate from articles of clothing, as some do. Many do not care about this, aiming to have every thing so clean when it has been washed, boiled, sun-dried, and ironed, that it may be put to almost any purpose. Each house-keeper must use her own judgment about what to put in first, or into the suds when it is clean. If white flannels are to be kept clear and white, they must be washed in clean suds, and rinsed in clean warm water; so never put them in at random among other clothes. As soon as you have taken out the last hot water needed for washing the white clothes, put more cold water in the boiler, and put into it the finest and whitest part of the white clothes. If you have used very strong suds in the washing, it is not necessary to put more soap into

the boiler, but most house-keepers do add soap, or soap and fluid. A thorough scalding is the main thing now. The water should be heated to boiling, and should boil from five to twenty minutes, according to the quantity of clothes in the boiler. Long boiling in suds makes clothes yellow. After the clothes are thoroughly scalded through the mass, I see no benefit in continued boiling. Stir them about, (or poke them down), with a clothes-stick. Set an empty tub near the stove, and take clothes from the boiler into this with the stick. When the tub is again on its bench, pour into it two or three pailfuls of cold water. Put another lot of clothes into the boiler, and proceed to "suds" the first lot. That is, rinse them well—rubbing wrists or children's drawers if not yet clean, and wring them. Take the others from the boiler, and suds them in the same tub. The sudsing water is then warm enough, and clean enough for washing the colored clothes. There is probably too much of it, and you can put some of it back into the boiler. If you have many colored clothes, you will need more than one suds for them. They should not lie in soak. White calico, with black figures, may be washed and boiled with the white clothes. Colored cotton or linen articles, may be rinsed in the water which has rinsed the white clothes, unless they are very dark colored or black, so as to show white lint, in which case they need clear water. They should be starched at once, and hung in the shade, if convenient.

Protection from Moths.

In May the clothes-moth begins to fly about our rooms. It is a small, light buff-colored "miller," dainty and beautiful on close inspection. Its highest mission seems to be to teach us to set our affections only upon incorruptible treasures which "moth and rust can not destroy." But it is necessary to keep a sharp lookout for the safety of our furs and flannels, and we must wage war upon it. In the first place we must carefully put away everything we can, upon which it will lay its eggs. If we pack away our furs and flannels early in May, before the moth has begun to lay its eggs, and leave them in boxes or bags so tight that the flying-moth can not squeeze in, no further precaution is necessary. Clean paper bags are recommended for this purpose—those used for flour and meal bags. They should be without holes or openings anywhere. These bags, when filled and closed firmly, may be put away on closet shelves or in loose boxes, without danger to their contents, so far as moths are concerned, without need of camphor or other strong odors to drive moths away. Furs are usually sold in boxes, in which they may be kept. Beat them well when you finally put them away for the season. If you delay putting them away until June, examine the furs well, and shake and beat them very thoroughly, in order that any moth-eggs that may possibly have been laid in them may be thoroughly removed or killed. Furs sealed up early in May need no camphor or tobacco or other "preventive." Muff and tippet boxes should be tied up securely in bags, or made safe by mending holes and pasting a strip of paper around the junction of the cover with the box below, so as to close all openings. Woolen garments must not hang in closets through the summer, in parts of the country where moths abound. They should be packed away in tight trunks or boxes, or sealed up in bags. Woolen blankets must be well shaken and carefully put away, unless they are in daily use. Early in June the larvæ of the moth begin their ravages, and now, unless you who dwell in places where clothes-moths are not found, look sharp, you will find some precious thing that you have forgotten—some good coat unused for a few weeks, or the woolen cover of a neglected piano, already more or less riddled by the voracious moths. It is their nature to eat until they have grown strong enough to retire from the eating business, and go into the chrysalis condition.

Some things can not well be packed away in tight boxes and bags, and among these it is well to scatter small lumps of camphor or clippings of Russia leather. Some use tobacco, though I think

camphor is usually preferred. It is said that powdered black pepper, scattered under the edge of carpets, will preserve them from attacks. Dr. Harris says that "the cloth lining of carriages can be secured forever from their ravages by being washed or sponged on both sides by a solution of Corrosive Sublimite in alcohol, made just strong enough to leave a white stain on a black feather."—I have lived most of my life where none of these precautions were necessary, but I shall never forget the shame I felt, during the first year of my house-keeping, when I discovered the wide-spread damage done in my house, before I had even thought of such a thing as moths.

Care of Winter Bed-clothes in Summer.

In a sister's letter I find some good suggestions about the proper keeping of unused bedding. Before she came West she had plenty of good roomy closets, but now she lives in a house with only one small clothes-room. So she manufactures closet-room out of dry goods boxes. A medium sized box, turned up on one side, with cleats nailed on the ends inside the box, for two shelves, affords room to pile away her bed quilts nicely folded; and then she covers them with newspapers, tucked under all across the front, so as to exclude dust. From the top of the box she hangs a curtain, and covers the whole with a cloth or with paper, using the flat top for a table to lay piles of papers and magazines which she wishes to preserve. I have previously described a table made of a dry goods box, by turning it on its side and elevating it on legs. Such tables are excellent places for packing comforters and quilts. The bed-clothes should be well aired on the clothes-line in the sunshine, before putting them away. If blankets are packed away in these box tables, they must be especially guarded from moths, as previously directed.

Bean Soup.

A friend recommends this as the best: Soak the beans over night. Boil three hours, or until very soft. Strain them through a colander and, after placing the soup again over the fire (to heat, but not to boil more than a minute), season for one pint of beans as follows: One teaspoonful each of sugar and salt, half teaspoonful pepper, teacupful of milk, one tablespoonful of butter, and one beaten egg.

Potted Ham.

In warm weather it is difficult to keep ham that has been cut. The following plan is safe and good. Cut all that will make good slices, and fry as for the table. Lay the pieces close and even in a stone jar, packing them snugly and pressing them down. Pour all the hot fat over them, to fill the spaces and exclude air. Lay a plate over the top with a stone upon it. Keep in a cool, dry place, and you will find it nice and convenient all through warm weather. When wanted for the table, lay slices in the frying-pan, and only heat them through without more cooking. Be careful to keep the top of the jar covered carefully, so that flies may never gain an entrance.

How to Bake a Ham.

A good way to cook a ham, is to bake it. Soak about twelve hours. Wash very clean, trimming away any rusty parts. Wipe dry, and cover the part not protected with skin, with a paste, or dough made of flour and hot water. Lay in a dripping-pan, with the paste-covered side upwards, with enough water to keep it from burning. Bake until a fork pierces it easily, allowing about twenty-five minutes to each pound of the ham. Baste occasionally with the drippings, to prevent the crust of paste from cracking off. When done, peel off this crust and remove the skin of the ham. It may be served as it is, or it may be glazed.

To Glaze a Ham.

Brush the ham over with beaten egg. To a cup of finely powdered cracker, allow enough rich milk or cream to make into a thick paste, add a little salt, and work in a teaspoonful of softened butter. Spread this evenly over the ham, a quarter of an inch thick, and set it in a moderate oven to brown.

Rhubarb Pie.

Some very early Rhubarb, with tender red stems, does not need scraping or skinning, or anything but

simply washing; but usually the first thing to be done, is to strip the stems of the tough skins. Cut into half inch slices, and lay them evenly on the undercrust. Scatter over this a teacupful of sugar and a tablespoonful of flour. Wet the edge of the undercrust all around, and press the edge of the uppercrust neatly to it. Dip the fingers in flour and pass around the cut edge, to make it close well, so that the juice will not be lost. Care is needed that it does not bake too fast (the most common cause of running over), yet it does not want a slow oven.

Gardening for a House-keeper.

"Mrs. J. R. S." goes to the country in May, and stays until October. They keep a man to care for the horse and cow and the vegetable garden. "Mr. S." comes from the city at evening, and goes back

Fig. 1.—DESIGN FOR FLOWER-BEDS.

in the morning; and whatever of flower gardening is done, must be done by the Madame herself, with such help as the man can afford. The cottage has a fair-sized front-yard, with grass in very good condition; there are a few shrubs, but they all flower early, and are soon done with, and she wishes to break up the uniform green, and put a spot of bright color on the lawn, but she would do this at a very little expense, and with the least possible labor. No doubt this is the case with many other house-keepers—they would like to know how they can do a bit of ornamental gardening inexpensively, both as to outlay of money and labor. For such purposes, they must rely upon Annuals, and to produce the best effect, these should be in masses. The accompanying diagram, fig. 1, is of some beds made a few summers ago by a neighbor of ours, which were very successful, indeed more effective than the gardens of some of her neighbors, where a gardener was kept, and a vastly greater expense incurred. Here we have an oval bed, with a curved bed at each side, and a small circular bed at each end; the simple outlines are in much better taste than the stars, hearts, and such figures as are often attempted. It is not easy to make an oval by the eye, but very easy with two sticks and a string, as shown in figure 2. At *a* and *b* are two stout sticks, put firmly in the ground. The dotted line is a cord, or strong twine, made fast to another stick at *c*, which is to serve as a marker. By moving the stick *c* in either direction, keeping the cord tight all the while, a regular oval may be traced, which will be narrower or broader, as the cord is lengthened or shortened. On the bare ground, the outline may be scratched by the stick *c*; but as the bed is to be made in the grass, a number of sticks, one say for each foot or so, will be needed—bits of lath, or any twigs, will answer; these sticks are to be used to mark the outline, and one is to be stuck into the ground every foot or so at the places indicated, by moving the stick *c*. When the outline is satisfactory, the turf should be carefully

Fig. 2.—OVAL.

cut with a sharp spade, following the sticks as a guide, and taken up and removed. It will then be easy to lay out the two curved and two circular beds, which should have the turf removed from them in the same manner. In the case referred to, the oval was four and a half feet wide, the two circles four feet across, and the curved beds three feet wide; the width of grass left between the different beds was two and a half feet, to allow the mowing-machine to be readily used. If the turf has been neatly taken off, probably no soil need be added; some well-rotted manure should be given, and the beds well forked over, and the soil made fine and mellow with the fork and rake. Now for filling the beds. The center one was filled with the *Petunia*, the "Countess of Ellsmere," which is one of the best bedders; a rather small flower, but of good substance, of a deep rose-color, with a white throat, and very lively. This may be had of most seedsmen, but, of course, any other will do, if preferred. For the curved beds, two colors of *Phlox Drummondii*, the catalogues allow quite a selection. For the circles, both may be filled with *Dwarf Convolvulus*, the bright blue or purple variety. These selections can be varied indefinitely, but those named are of annuals that are really effective, and, what is quite important, last long in bloom. They may be sown in the beds, and thinned afterwards, but it would be better to sow, at least the *Petunia* and *Phloxes*, in boxes, the seeds are so fine; and when the plants are large enough, transplant to six or eight inches apart each way, all over the beds. If a bolder effect is desired, a Castor-Oil plant may occupy the

center of the oval, surrounded by the Striped Japanese Maize, the four outer beds being planted as before suggested. Either of these arrangements will be very brilliant and satisfactory, at an outlay of only 50 cents for seeds.

Women's and Children's Shoes.

"R. K.," Hartford, Conn., wishes a recipe to make a dressing to use upon the shoes of the women and children; one that "will polish, will not crack, and will be good for the leather." There are various preparations sold, but R. K. is tired of buying them, as their chief expense is for the bottles, which when empty accumulate, and are not useful for any other purpose. The only article of the kind with which we have had much experience, is the old-fashioned "Sponge-Blackening," which has been in use for a half century or more. It is simply a Shellac varnish, and is probably not especially "good for the leather"—a matter of not much importance for the shoes of women and children, the uppers of which, under any circumstances, outlast the usually thin soles. To make this, put half a pound of gum shellac in a wide-mouthed bottle, or fruit jar, and cover it with strong alcohol; loosely cork, and set this in a sauce-pan of cold water, placing under it a small piece of board, a couple of sticks, or whatever will keep the bottle from direct contact with the bottom of the sauce-pan. Set the pan on the stove, and allow it to heat up gradually, and keep the water at the simmering point, stirring from time to time with a stick, until the shellac is dissolved, which it should be in half an hour or less. Recollect that the vapor of alcohol is very inflammable, and it must be kept from contact with the fire. When the shellac is thoroughly dissolved, remove the bottle from the sauce-pan, and add one ounce of lamp-black, stirring thoroughly, until all lumps are removed. If too thick, as it is likely to be, add more alcohol to make it thin enough to apply readily with a brush, or by means of a sponge attached to a wire. Keep well stopped, and if it becomes thick by the evaporation of the alcohol, add more. This applied, as a varnish, to leather, rubbers, etc., dries at once,

and leaves a bright gloss. It can only injure leather mechanically, several coats will make it stiff, which may be avoided by occasionally oiling the leather.

A DRESSING FOR PATENT LEATHER.—When patent leather boots or shoes lose their original lustre, they may be revived by a very simple dressing. Sugar one pound; Gum Arabic, in powder, one ounce; Ivory-Black, one pound. Add a pint of water, and boil together, stirring, until the Gum and Sugar are well dissolved. If too thick to apply smoothly, add more water. Let stand for a few hours for the coarser portions of the ivory-black to settle, then pour off and bottle. This is to be applied to the patent leather with a soft camel's-hair, or badger-hair brush. When a new application is to be made, the former coat, if too thick and stiff, may be removed by washing it off with a damp cloth. This renews the lustre of patent leather perfectly, and was given us by a gentleman from Europe, who paid his French valet a round-price for the secret.

Household Notes and Queries.

A GOOD PREPARATION OF VEAL.—This being the "veal season," the following is an excellent mode of preparing it to be eaten cold, and for keeping it on hand for several days, ready for immediate use: Take say 3½ lbs.—the thick part of the leg is preferable, with the tough tendinous parts removed—chop it fine without cooking; mix well with it 4 soda crackers rolled fine, 3 well-beaten eggs, 1 tablespoonful of salt, 1 teaspoonful of pepper, ½ nutmeg, 2 tablespoonfuls of cream, or a small piece of butter. Make it into a loaf, and bake in a dripping-pan without water, with quick heat at first, to close the outside and retain the juices, and continue the baking about 1½ to 1¾ hour. Serve out in thin slices. An excellent lunch in traveling.

ANOTHER WAY TO COOK VEAL.—In England everybody goes to the races, and great preparations are made for the lunch on those occasions. Veal prepared in this manner is a favorite at the race lunch, but will be found useful at other times. Butter a good sized bowl, and line it with thin slices of hard-boiled eggs. Have veal and ham both in very thin slices; place in the bowl a layer of veal, with pepper and salt, then a layer of ham, omitting the salt; then a layer of veal, and so on alternating with veal and ham until the bowl is filled. Make a paste of flour and water, as stiff as it can be rolled out; cover the contents of the bowl with the paste, and over this tie a doubled cotton cloth. Put the bowl into a saucepan, or other vessel, with water just up to the rim of the bowl, and boil three hours; then take it from the fire, remove the cloth and paste, and let it stand until the next day, when it may be turned out and served in very thin slices.

GASOLINE.—"C. T. M.," Bolivar Co., Miss., asks: "Is Gasoline any more dangerous to use for burning than coal-oil, and what is its composition?"—Without knowing what our correspondent means by "coal-oil," we can answer that Gasoline is eminently—fearfully dangerous, and should not be used in any lamp whatever. To answer his question as to composition in general terms, we may say that Petroleum, as it comes from the wells, is a mixture of several distinct compounds of carbon and hydrogen. The products from different localities vary greatly, but they are all mixtures of hydro-carbons, which are distinguished especially by a great difference in their boiling points. If petroleum be placed in a still, and heat gradually applied, first *Rhigolene*, will pass off. This has the lowest boiling point of any liquid, as it boils at 65° Fah. Then when the heat is raised to 120° Fah. Gasoline will pass off. At 180° *Naphtha* will be distilled; of this there are three kinds; one boiling at 180°, another at 220°, and another at 300°. When the heat is raised to 350°, the liquid which passes off is known as *Kerosene*, and there are others that boil at higher temperatures than this. This is the only petroleum product that can be safely used, and Gasoline or Naphtha alone, or, as they unfortunately sometimes are, mixed with Kerosene, should be avoided. While there are contrivances for burning the vapor of Gasoline mingled

with air, as a substitute for gas, and for aught we know, some of these under proper management may be safe, there is no way, no lamp, in which the liquid *Gasoline*, or either of the *Naphthas* can be safely burned. Who ever does this, assumes a risk he has no right to take, and exposes others to dangers fearful to contemplate. Let them all alone!

YEAST.—"Mrs. C.," of Hawley, Minn., finding the preparation of the yeast, in providing bread for a large family, to be no little labor, has simplified the matter as follows: "When the potatoes are boiled for dinner, I pour the water in which they have been cooked into a pitcher, setting it aside to cool. By the time dinner is over, it is about the proper heat. I then add a tablespoonful each of sugar, salt, and flour, mix together thoroughly, and pour this into the yeast-jar, which, of course, has left in it some of the old yeast. In this way I have always fresh, good yeast on hand, with comparatively no trouble."—This is not very definite as to quantities—of course it refers to water from peeled potatoes; but the plan of adding fresh materials to the yeast-jar is a good one.

COTTAGE PUDDING.—"H. M. J." If one wishes to prepare a dessert hurriedly, or when an unexpected visitor comes on a day when the dinner is somewhat meagre, this pudding answers an excellent purpose, as it is easily and quickly made, and "very filling for the price." The materials required are: Flour, three cupfuls, or sufficient to make the batter; Butter, one tablespoonful; Sugar, one cupful; Eggs, two; Milk, one cupful; Soda, half a teaspoonful; Cream of Tartar and Salt, of each, one teaspoonful. Mix the Cream of Tartar with the Flour, beat the Whites of the Eggs together, then work in the Milk, Soda, and Salt, adding gradually, the Flour and Whites of the eggs. There should be flour enough to make a fairly stiff batter. Butter a mould or dish, and bake. It may be turned out, or served from the dish. To be eaten with any liquid sauce.

LEMON PIE.—The grated rind and juice of one Lemon, one teaspoonful each of White Sugar and boiling water, one tablespoonful each of Butter and Corn-starch, one Egg. Begin by creaming together the butter and sugar. Mix the corn-starch with a little cold water, and stir this into the boiling water. Pour this hot starch mixture over the sugar and butter, stirring together. While it is cooling, heat the egg and prepare the lemon. Stir all together, and bake with one crust.

CARPET MOTHS.—"W. W. B." We have published it once before; but it is seasonable, and we will give it again. These moths are mostly under the edges of the carpet, but take refuge in the cracks of the floor and under the base-board. Fold a sheet or other cloth to a handy size, wet it, and lay it upon the carpet; then have several flat-irons quite hot, and iron the cloth. This will drive the steam through the carpet and into all the cracks. By persevering with this, at intervals of a few days, to catch those that have hatched after the application, you will soon overcome them. Repetition is important in all battles with insects, as eggs often escape the treatment that kills the insects.

RECIPES WANTED.

A house-keeping friend asks for a recipe for making *SCRAPPLE*, said to be a popular breakfast dish in Philadelphia. We think it is a modified kind of head-cheese—will some one tell how to make it?

APPLE DUMPLINGS, STEAMED.—"Mrs. H.," of Niagara Co., N. Y., fails to make Steamed Apple Dumplings to exactly suit the taste of "Mr. H." Will some of her house-keeping sisters help her?

RYE FLOUR.—"Mrs. A." of Erie Co., N. Y., would like to know the best method of making Rye-bread, and for using rye flour generally. They can raise excellent rye, but have to buy all their wheat.

"SALT-RAISING."—"A Subscriber," very sensibly prefers "yeast-bread," but would like to know how to make other kinds to use in an emergency.

"THE QUEEN OF PUDDINGS."—"Mrs. D.," of Brenham, Texas, saw a recipe for this, several years ago. Can any one give us the recipe to publish it for the benefit of her and others?

BOYS & GIRLS' COLUMNS.

Aunt Sue's Chats.

A CARD-BASKET.—"K. B. W."—I know of no better pattern for "a card-basket of perforated card-board," than

Fig. 1.—PATTERN FOR CARD-BASKET.

that with a hexagonal base and six five-sided pieces around the sides. Figure 1 shows you half of the sides sewed upon the base. Let each side of your hexagon be exactly one inch and three-quarters wide. Cut your side-pieces of the shape of figure 2. (You will see the dimensions marked upon it.) Bind the pieces around, with narrow lute-string ribbon. You can either work some little design on each piece with silk or worsted, or you can stick a little picture upon each. Overhand the pieces together (as seen in fig. 1). Be careful to sew to the

Fig. 2.—ONE SIDE OF BASKET.

hexagonal base the side of the five-sided piece which measures 1¾ inches. A little bow of lute-string at the top (inside) of each side seam, will add to the effect.

RED JAPAN VARNISH.—"J. D. F."—The simplest way to make this, is to procure a stick of the best red sealing-wax, break it into small pieces, and drop it into a wide-mouthed bottle; then cover the sealing-wax with strong alcohol; cork the bottle, and set in a warm place. When thoroughly dissolved, it will be fit for use. You can dip your little twigs in it "to make them look like coral." The varnish soon dries, so you can give several coats, if needed, without much trouble. Poor sealing-wax will make an unsatisfactory varnish. Buy of a stationer, who knows what a good article is.

POLISHING SHIRT-BOSOMS.—SELMA wishes me to tell her "how to give a glossy appearance to shirt-fronts and collars, such as they have when new."—I can tell you, Selma, how to make the starch, but a great deal depends upon the ironing. Make a quart of starch the usual way, but see that it is very smooth and very thoroughly boiled. While hot, stir into it a piece of spermaceti, about as large as a hickory nut; then add a tablespoonful of gum-water, and stir all well together. You can always keep the gum-water prepared. The proportions are, two ounces of gum Arabic to one pint of water; but you had better make only half the quantity if you use it but once a week, as it spoils, especially in warm weather. But after making the best possible starch, you can not make the linen look "like new" without a "polishing-iron." These are sold at the furnishing stores, and are like a common flat-iron, but with rounded edges, and a highly polished steel face. It is hard rubbing with an iron of this kind that gives the new articles and those from the city laundries their peculiar gloss.

CRACKERS.—BELTINE had no success with her crackers; who will tell her how to make them?

I. T. E. asks me for a "description of printing done in old times, materials used," etc.—Some say that the Chinese printed from engraved blocks of wood, fifty years before the Christian era. Then we hear of it in Venice in the fourteenth century, where they fastened a page of manuscript on to the face of a block of wood, and engraved

the letters as written. In 1450 metal blocks were substituted for wooden ones. Peter Scheffer (son-in-law of John Faust) introduced movable metal type. The Mentz Bible is the first important specimen of metal-type printing, supposed to be published between 1450 and 1455. The Italic type was the invention of Aldus Manutius, the celebrated printer at Venice, about 1500, and dedicated by him to the States of Italy, from which it took its name.

I. T. E. sends a puzzle for the little ones to draw on

Fig. 3.—PUZZLE DRAWING.

their slates, (see fig. 3). They are to draw it without crossing a line, and without removing the pencil.

THE CAT AND THE RATS.—It is quite a long time since the cat and rat problem had a run, so we will start it on its rounds again. D. F. B. sends it to us this time. If 3 cats kill 3 rats in 3 minutes, how many cats will it take to kill 100 rats in 100 minutes?—I shall be happy to receive solutions to this.

Thanks, for letters, puzzles, etc., to Lee Sharp, H. S. Bean, H. Ashland, Jacob H., F. D. C., Benny, Lizzie D., Martin M. S., Cyrene G., "Rev." Monticello. (I am always pleased when the seniors join in the fun), and to Theo. F. S.

The Doctor's Correspondence.

I have been expecting it, and it has come at last—indeed, several have come—requests that I would tell the youngsters

"All About the Telephone."

Those who request another to tell them "all about" anything, have little idea how much they ask. Very few people in this world know "all about" anything. I say that I expected the request, because so many accounts of the wonderful doings with the Telephone, have been given in the papers all over the country, that I was very sure that some of my youngsters would wish to know about it. So before the first of the requests came, I examined the Telephone very carefully, intending to say something about it, even if you did not ask, for it is really a wonderful thing, and a great wonder about it is, that the accounts, for once, have generally been very true. In the first place we must ask

"What is a Telephone?"

for there are several of them. Its name gives a hint as to its use. You know that a *Telescope* allows one to see things that are far off; a *Telegraph* allows one to write at a great distance, and you are prepared, from the resemblance of the word *Telephone*, to know that it has something to do with distances. The name means to sound a-far off, but with the present instruments it is not merely a sound, but it carries voices and words, and by it persons can converse when miles apart. When I first saw the Telephone, I went to the "Tribune" Building, which is just across the Park from the office of the *American Agriculturist*, and there found Mr.

THE STREET TELEPHONE.

Applebaugh, whom I had known in telegraph matters, in charge of the Telephone. Although he has to do with *Tele*, or "far off" things, he is by no means a *distant* person himself, but showed me the *Tele-phone* inside and out. A wire extended from his office up to the building of the American Institute, where the Fair was being held, and distant three or four miles, at least. He took up a sort of wooden pepper-box, and introduced me to a lady at the Fair. He gave me another pepper-box to hold to my ear, and I heard very distinctly that the lady was "very glad to see me," though how she could

"see" through three miles of brick buildings, I could not understand. We talked a while, every word being perfectly distinct, and after that Mr. A. asked her to sing, when "Red, White, and Blue," was very neatly done; then another lady having joined the one at the Fair building, I had a pleasing duet. These are some of the things the Telephone will do, and you want to know

"How Does It Do It?"

The Telephone is no new thing, for there were attempts of the kind years and years ago, but it is only of late that it has been a success, because Prof. Bell, and others, have hit upon the present way of doing it. To understand the Telephone now in use, you must know a little about electricity and the magnet, and something about the laws of sound. Let us leave the electricity for the present, and see how much you know about sound.

Why Do We Hear a Sound or Noise?

Something must set the air in motion before we can hear anything. If you throw a pebble into still water, you see the little waves form a circle, which spreads, and spreads, so that after a while they strike the shore or spread so that you can not see these rings of waves, they become so small. When you clap your hands, you make similar waves in the air to those the stone makes in the water. They spread in all directions until they strike some one's ear; the waves of the air hit the "ear drum," which is like a drum-head. A stretched membrane, or kind of skin, that takes on the motion from the waves of air, sets some little bones—very curious they are, too—to shaking, and finally the disturbance in the air, caused by your "spatting" your hands together, gets through the ear-drum, the little bones and other parts of the ear to the brain of another person, and he *hears* the noise. Sounds of all kinds, from the least whisper, and the softest musical note, to the thunder, all come to our brain—are heard, through a disturbance in the air, which is set in motion in one way or another. Now the Telephone is a contrivance for disturbing the air in a particular manner, so that it will repeat the sounds of music, or of a voice, at a great distance—50, or 100, or more miles. The contrivance by which this is done, I must tell you of at another time. The Telephone repeats a sound at a distance, by the vibration of—what do you suppose?—a plate of iron! The arrangements of the very simple parts for doing this, I will try to show another month. That vibrations caused by the voice may be carried a long distance, is shown by the little toy now called the "Street Telephone," but which, a few years ago, was sold as "The Lovers' Telegraph." This is easily made of two tin cylinders; mustard, or spice boxes, with the bottom knocked off—placing the box on the stove, until the solder which holds the bottom is melted. Over one end of each cylinder is tied a piece of wetted parchment (no doubt bladder would answer as well); this, when dry, will be as tight as a drum. Now take a small cord, or twine, 50 or more feet long; make a small hole in the center of each parchment head, pass one end of the cord through, and make a knot on the other side—or inside—to hold it; the engraving shows the thing, but not the whole length of the cord. To use this, two persons, each taking one of the tin drums, and *stretch the string a little tight*. One talks into the open end of the tin, while the other holds his to his ear. The voice sets the parchment to vibrating; these motions are carried along the string, and set the other parchment into the same kind of motion, and this allows the ear of the other to hear what was said quite plainly. This is but a toy, but it shows one way in which words may be carried to a distance.

BIBLICAL ENIGMA.

I am composed of 28 letters:
My 5, 24, 1, 13, 8, 12, was a city celebrated for its commerce and literature.
My 9, 4, 16, 1, 27, 23, a beautiful, fertile plain of Palestine.
My 14, 17, 2, 15, 26, 1, is the refined spirit or quintessence.
My 17, 11, 3, 2, 7, 10, a band of soldiers in the Roman army.
My 22, 18, 21, 6, 28, 9, is a European city.
My 25, 16, 17, 19, 10, 20, was an ancient measure of money.
My whole is part of a verse of Proverbs. ISOLA.

NUMERICAL ENIGMAS.

1. I am composed of 45 letters:
My 21, 35, 43, 1, 12, 26, 45, 31, is a celebrated philosopher.
My 41, 17, 37, 7, 9, 24, is the name of a prophet.
My 19, 28, 44, 5, 23, a city in France.
My 22, 14, 8, 40, 6, 4, 25, 42, is something we all have of which no one can rob us.
My 16, 13, 2, 33, 36, 20, is a bird.
My 32, 3, 38, 34, 45, 39, is a constellation.
My 15, 10, 27, 30, 6, 14, 9, is a country of old Europe.
My 25, 11, 34, 18, 29, 9, is a city of Greece.
My whole is all too true. FANNY BOND.

2. I am composed of 10 letters:

- My 1, 2, 7, is a pronoun.
- My 6, 10, 3, 9, is a fruit.
- My 9, 8, 4, 10, is a tool.
- My 5, 2, 7, 10, 6, is an animal.
- My whole is a well-known author.

KATE J. CURTISS.

3. I am composed of 13 letters:

- My 4, 2, 9, 6, 10, is a fastening.
- My 4, 2, 9, 10, 5, is a machine.
- My 4, 2, 1, 10, is a stick of wood.
- My 3, 8, 7, 9, is a bar for fastening.
- My whole is an article of every day use. J. & C.

4. I am composed of 17 letters:

- My 8, 6, 7, is a girl's nickname.
- My 5, 2, 9, 9, 13, 14, is a plant.
- My 1, 3, 4, is an insect.
- My 11, 14, 1, 13, is ardor.
- My 12, 16, 3, 14, is a girle.
- My 15, 7, 1, 10, 17, are much discussed by young ladies at boarding-school.
- My whole is something to which we all look forward with interest and pleasure. SYDNORA.

Send communications intended for Aunt Sue, to Box 111, P. O., Brooklyn, N. Y., and not to 245 Broadway.

The Young Microscopist's Club.

I supposed that the contrivances for mounting the American Agriculturist Microscope, had all been given. I recollect that I said, in one of the former articles, that the chief thing was to get the lenses, and that when one had these, he could mount them in ways to suit his needs. Several methods of mounting the Microscope (my own and others) have been given, and now here comes one that shows so much ingenuity, and also

knowledge of the Microscope, that I must give it in brief, allowing the engravings to show the details. This comes from Mr. E. W. Kilbourne, Agent of the American Express Co., Green Castle, Ind. He does not ask me to suppress his name, so I give it here, as an acknowledgment of his ingenuity. He writes a very full account, which I give in my own way, and makes very plain drawings, which are here engraved. Mr. K.'s object is to so mount the Microscope, that it can be readily used for both opaque and transparent objects, and also to allow it to be inclined to any desired angle, which is often

A Great Convenience.

The first thing required in Mr. K.'s mounting, is a heavy foot of hard-wood; this may be one inch thick, and six inches square. This is shown in *g, h*, figure 1. The Microscope is mounted upon a base, 3 x 4 inches, and of 1/4 to 1/2 inch in thickness; this has an opening 1 1/2 inch square cut in it, over which the Microscope sets; this base is seen more distinctly in figure 2, where it appears as if looked down upon. The Microscope is held in place over the opening by means of three large-headed carpet tacks. One of these is placed at the dot marked *l*, (fig. 2), and the other two at *k* and *p*; the tacks are not to be 'driven home,' but left so far above the surface of the wood, that the hard rubber base of the Microscope will pass between them with a slight push. The important point is to so attach this base, holding the Microscope to the heavy wooden foot, that it may be inclined at will; this Mr. K. ingeniously does by

The Use of Curtain Fixtures.

At figure 3 is shown a common bronze casting, such as is used to hold up the end of the roller to a window shade or curtain. Two of these castings are attached to the heavy foot (*g, h*) by means of screws, and just far

enough apart to allow a third to be placed between them.

Fig. 3.—CASTING.

sition of the parts, as seen from the front: *c, d* is the foot; *a, b*, the base; *g, h, i*, the three curtain fixtures, through the eyes of which is passed the stove bolt, *a, p* (to be had at the stores for 2 to 4 cents). In case, as will usually happen, the bolt is too long, a common spool (*y*), or a part of one, may be used as a "washer," between the castings and the nut, *o*. This contrivance may be varied by using thick leather washers between the three castings, and between one of these and the head of the bolt, and between the other and the nut. The object of the arrangement is to allow the base, to which the Microscope is fastened, to be placed at and held at any angle. This accomplished, Mr. K.'s next point was to so

Arrange a Mirror

that he could readily throw light upon any object under examination. This he does in a very simple manner. Beneath the base to which the Microscope is attached, as already described, is fastened a bottle-cork, by means of a strong wire running through it, bent at right angles below, and bent twice above, so that one end may be driven into the base to hold it in place. This arrangement is shown in figure 5. To hold the mirror, the strong wire *w*, is provided, which passes through the cork, and has soldered at one end a piece of thin tin plate (*a, b*) to hold the mirror, and at the other end a nickel cent, or any other contrivance to answer as a head by which the wire may be easily turned. The mirror—a piece of looking-glass—is held in place by turning down the corners of the piece of tin (*a, b*) to catch and hold it. It will be seen that by this arrangement the mirror can be rotated, and by revolving the cork upon its wire, it can have a right and left motion; by these two motions the light from the mirror can be greatly varied, as for

Fig. 5.—ARRANGEMENT OF MIRROR.

some objects an oblique light is better than a direct one. Mr. K. says that the whole outfit, soldering and all, cost him but 15 cents, and he finds this manner of mounting much preferable to that upon a cigar box, as before described. Those who can not readily get the curtain fixtures, can make a similar mounting of all wood, as shown in figure 6, where *a, b* is the base, *c, d* two wooden posts fastened to it; between these is another similar post, *f*, attached to the foot which holds the Microscope; this goes between the two lower posts, and through all three passes a bolt with a nut. The mirror and all other arrangements are to be as already described. I supposed we should not have any new mountings to describe, but this of Mr. Kilbourne is so ingenious, and so much easier to carry out than it looks, that I thought it would please many of you. Still I must not forget to speak of

Objects to be Looked for,

and as in this I have kept well ahead of the season, most of you will be likely to find the objects mentioned last month, and in March and February, now, rather than earlier; but in these matters I have to recollect that there are youngsters who are enjoying spring, while others have not put away their sleds and skates. Objects will now be so abundant that you will hardly

need to have them pointed out. This month, in the Northern States, will be a great time for fishing in the pools and ditches before they dry up, as most of them do before long. You have not, I hope, forgotten the Frog-spawn and the Snail's-eggs, described in March. If you take a glass jar, such as fruit is preserved in, and dip it full of water as suggested last month for finding the *Volvox*, or "Revolving Globe," you will be very likely to catch one or more kinds of what are called

"Water Fleas."

They are not Fleas though, but belong with the shrimps, crabs, and lobsters, in the class called by naturalists, *Crustaceans*. To get some specimens from which to make a drawing, I sent Master Ferdie to a pool I had noticed a short distance down the road, to get a jar full of the water. He came back, thinking that he had caught nothing, but upon holding the jar up to a strong light, I showed him that he had a regular menagerie of "Water-Fleas."

Fig. 7.—WATER-FLEA.

These creatures are called "Water Fleas" from the jerking manner of their movements, for they do not swim in a straight-ahead-way, but go by jumps. To draw one of these creatures, it had to be caught with the Dipping Tube, described last month, (fig. 9). Placed in the cell of the Microscope, with a few drops of water—enough to allow it to move about, it could be readily examined. This particular "Water-Flea," and you will no doubt find others, is called by naturalists *Daphnia*. A thin, transparent shield covers the animal, but it is open at the lower edge, and allows the parts of its body to protrude, as you can see when it jerks out its tail and other parts. If you catch a female, you will be very likely to find some eggs, which she carries between her shell and her body. The most common of our "Water-Fleas" is shown in figure 7. Among the curious things to be looked for now, are

The Vorticellas

which you may often find in pools, attached to chips and other matters. If you find on a stick, leaf, or other thing from one of these pools, a mere speck of cottony white stuff, you will possibly find the *Vorticella*. I have rarely failed to find it on the stems of flowers that have been kept in water for a long while, or you may make

Some Hay Tea,

and be very sure to get this, and other curious creatures, after a while. Make a wisp of hay, place it in a dish, and make an infusion, or tea, by pouring hot water over it; then let it stand for some days. The creatures thus found in infusions of vegetable matter, were called *infusoria*, a term which you will find in use for minute animals of various kinds. The *Vorticella*, or the one I have usually found on the hay, after it has been in steep for several days, is shown in figure 8, as it appears under the Microscope. It has a bell-shaped body on a long stalk. The mouth of the bell has a fringe of hairs; these being kept in constant motion, carrying water into the bell-like body, and with it creatures still smaller than itself, upon which it feeds.

Each bell is attached to a stalk, which can on the instant coil itself in a spiral, and bring the bell-shaped part, which also shuts up, down to the point where it is attached. I know of no more curious creatures than these, and which, with a fair amount of patience, you can find either on decayed vegetable matter in pools, or can breed, as I have described, in an infusion of hay. It is a little late in most places for the flowers or "tags" of the Alders and Hazels, but where these, and

Fig. 8.—VORTICELLA.

The Willows and Poplars

are not gone, you will find them worth examining. You will see that all, whether the "tags" upon Hazels, Alders, Poplars, and Willows, are each made up of a number of scales, underneath which you will find stamens only in the first two, but the tags may, in the willows and poplars, have either stamens or pistils, but only one kind in the tag from each tree. But most of you will like to look at flowers made more after the regular style than these. You will find very early, almost as soon as the snow goes off, the Chickweed, and its relatives, the Mouse-ear Chickweed. The flowers of these are very small, to be sure, and I mention them because, though small, they are quite as perfect in their way as any flowers. It is very likely that you may find some notes about the Microscope among the Basket Items. THE DOCTOR.

Fig. 6.—WOOD-FIXTURE.

Fig. 2.—BASE.

Little Gardeners and Little Gardens.

When we saw the picture given below of the "Little Gardeners," in an English magazine, "Our Little Folks," we thought it one that would please our little folks, for no doubt there are already many little gardeners among them, and we wish to have many more. Every one of our *American Agriculturist* family of youngsters should have a garden of some kind, and grow something. Those who live in the country, where land is not counted by feet and inches, but where there is so much room that there is no trouble as to the space, should be sure and have a garden of good size. Those who live in villages,

where each house has a good sized yard and garden, can no doubt, if they ask for it, and agree to take care of it, have a small hed—a few square feet that they can call their "garden." But we must not forget that a great many of our readers live in cities; the parents of many of our youngsters, who are in crowded towns and cities, take the *American Agriculturist* because they expect to move into the country at some future time; others because they were brought up in the country, and love to read about it; others for its useful articles in addition to soil culture; and so in this way we have many readers among city children. What shall these do for a garden, whose back yard is hardly large enough to allow of the drying of the weekly washing? They must take to window-boxes, or even to pots, and whatever will hold earth. They can make a very good window-garden in a common wooden box, 6 or 8 inches broad and deep, and as long as the window-sill. A box of this kind, strongly

nailed all around, and filled with earth to within an inch or so of the top, will allow of the growing of many interesting plants, and be a source of a great deal of pleasure. Of course, it would be better to have a regular garden with a plenty of room, in which to grow a great many things, but those who really love plants, will contrive to have them somehow, and will content themselves with even one, if no more are to be had. In the engraving we have a fine place in the country, with an abundance of room for the garden, and it is evidently a place where there is a gardener who has supplied the children with plants already partly grown in pots, which they have only to set out in the garden, where they will grow on and bloom. This is all very well for those who are so situated that they can have such things, and as on such places there is a gardener, the children who can make their garden in this way, will need no help from us, as the gardener will tell them what to do with the plants. But the great majority of our youngsters will start their garden, be it large or small—even a window-box, with seeds. Of course there are many desirable plants that are not raised from seed; the florists raise these from cuttings, and sell the small plants in little pots. Those who can afford it, can purchase these, but we will assume that in our "little garden" the plants are to be all raised from seeds. Did you ever think what a wonderful thing a seed is? No matter if a mere speck—like a Petunia seed, or as big as a bean—each seed is a perfect wonder. Though to all appearances, lifeless, dry, hard, and unpromising, expose it to the proper conditions, and a plant soon comes from it! We go to see wonderful tricks of magicians, who burn up a handkerchief, and afterwards return it all nicely ironed and perfumed, and wonder at it—but no trick ever played by the most skilled of these performers is half so wonderful as the production of a green, living, growing plant from a seemingly dead and dry seed. Yet this, which is almost a miracle, is so common, is constantly going on all about us, that we do not stop to think how very grand it all is. The farmer scatters what seems like dry and lifeless chaff, and there appear acres of green meadow—yet what happens in each little grass seed, is as wonderful in its way, as the motions of the planets. But before we talk of sowing the seed, and

what happens after it is sown, let us consider what we shall sow. Here we are met with a difficulty—young people have not, generally, much money to spend. We could take a seed catalogue, and pick out a list of the best—but perhaps most of you could not buy them. Many of you saved seeds last year, no doubt, and can exchange these with others who have done the same. Then many of you must know those who have gardens, who will willingly give you seeds, for real lovers of flowers are always liberal in this way. Still many, to get a start, must buy. The beginner should start with *annuals*—i. e., those plants which bloom the first year from the seed. Most seedsmen put up collections for 25c., 50c., or \$1, of the best annuals, and probably seeds may be had

are the principal points: 1st, "sufficient heat."—If you were to sow your Balsam, or your Portulaca seeds, as soon as the ground thaws, but while it was still cold, you would probably not find one to come up. The Sweet Pea, and some others, might stand this treatment, but as a rule, seeds should not be sown until the ground is well warmed. 2d, "sufficient moisture."—If you sow your seeds in perfectly dry soil, no change will take place in them; they will be at the end of one month, or six months, just as they were put in; place them in moist soil, but not wet, and they will soon swell, burst, and a little plant will appear, and this has a relation to 3d, "sufficient air."—We can not now give space to tell you all about seeds, or why they should need air; you

"THE LITTLE GARDENERS."—Drawn and Engraved for the *American Agriculturist*.

more cheaply in collections than in any other way. If about to start a garden at the least expense, we should buy the seeds in "mixed" packets, and thus get a number of varieties for the price of one; each packet of mixed seed will give several varieties, from which seeds can be saved for next year—the different colors being kept separate, and thus a large supply be had for another year. The catalogues of the seedsmen offer the varieties of each plant—Asters, for example, a dozen or more distinct varieties in separate packets; and then, "finest mixed" at the same price of the separate packets. If the mixtures are fairly made, and we have no reason to suppose that they are not, a packet of mixed seeds should give from three to six different colors, from which the seeds may be saved separately. Taking the popular annuals, our selection would be, for those sold at 5c. the packet, Asters; Balsams (Touch-Me-Not); Candytuft; Convolvulus (Morning Glories of the finer kinds, for we must have some climbers, you know); Mignonette (should be in every garden, for its fragrance); Sweet Peas (charming low climbers, and excellent to cut); Petunias; Drummond's Phlox (*Phlox Drummondii*, one of the most brilliant of all annuals, and in great variety); China Pinks; Portulaca; Stock Gilliflowers (called Stocks, the Ten-Weeks sorts are best); Double Zinnias (showy, large, and for the garden only). If some wish to expend more on a greater variety, they can easily do so, but we have in mind a small expenditure, and such plants as are likely to be satisfactory in a large or small garden, or even in a window-box, and we have tried to name such as will be showy in the garden, and for the most part, useful for cut-flowers. We know those who never cut flowers, but are great admirers of them as they grow in the garden, and others to whom a flower is of but little value if it can not be cut, and placed in a vase in the house, or made into a bouquet.

We have mentioned the wonderful things that happen, when the dry and apparently lifeless seeds are "exposed to the proper conditions." In starting our garden, we must know what those "conditions" are, as, having bought, or otherwise procured our seeds, we wish them to give us plants. We must have 1st, sufficient heat; 2d, sufficient moisture; and 3d, sufficient air. These

must accept this and some other things as facts. Ordinary moist soil contains an abundance of air; wet soil does not, as the water fills up the pores of the soil, the seeds will have too much water, and no air; hence they can not grow. So your garden should not be too wet; in most of the States it is not likely to be too dry. A very good general rule, is to sow your seeds in the open ground at the time the farmers are planting their corn. Though our garden talk is already long, there are two or three things yet to be said. A great fault is sowing the seeds too deeply. Large seeds, like those of the Sweet Pea, and Morning Glories, may be put an inch deep, while the finer seeds, as those of the Petunia, etc., are so very small, that sown so deep as this, they would never be heard of. Such fine seeds need but the slightest possible covering with earth. All the seeds above named, may be sown where they are to stay, but all except Morning Glories, Mignonette, and Sweet Peas, may be as well trans-

planted as not. It may be that some of you do not know what transplanting means, so we will explain it. The seeds are sown, and the young plants allowed to get an inch or so high; then these little plants are taken up very carefully, a cloudy, damp day being the best, and planted out where they are to flower. You can, if you choose, sow the seeds of all the others, in a box, pan, or pot of earth, in a sunny window, and then transplant the young plants, when they get large enough to handle, to the garden, or you can sow them in a nice spot in your garden, and when large enough, set them where you wish them to bloom. We are always apt to sow seeds too thickly, and it is well to thin them, and set out the plants taken up in the thinning, in another place. If you must transplant when it is not moist and rainy, water the seed-bed well, and also the place where the little plants are to be set. Then after the plants are put out, and the weather is sunny, you must shade the little things, which may be done with shingles set so as to screen them, or by newspapers, kept from touching the plants by means of some sticks stuck near them. To keep the papers from being blown off, put some earth on their edges. Having thus far started your little garden, by telling you about sowing seeds, which may be those we have named, or any others that you can get, what we especially wish you to do is to watch the seeds as they come up, and how the little plants behave afterwards. In some cases you will see a pair of seed-leaves, as they are called, and the next leaves that appear will be quite unlike these—the "rough leaves," as the gardeners say. Your Sweet Peas will show no seed-leaves at all, while those of your Morning Glories will be large, broad, and green. If you love your little plants, you will watch all these things, and we will try to tell you more about them hereafter.

PLANTS FROM CUTTINGS, or "slips," as they are called, are often easily raised. If some friend gives you a "slip" of a Geranium, a Rose, or other plant, you have only to set it in a pot or box of very light sandy soil; pure sand is better than stiff clayey soil, and give it a plenty of light, but not much direct sun. Keep the earth moist, and usually in two or three weeks (and with some others much sooner) it will push out little roots, when it may be set out in better soil in the window-box or garden.

EVERY LADY

In the United States can afford to spend 15 CENTS to learn what the Fashions are going to be, and the very **Lowest Prices** at which the coming Fashions can be purchased.

15 CENTS will make you a subscriber to the Spring Number of

EHRICH'S FASHION QUARTERLY.

A Magazine that differs from all others in that it presents no possible, probable, or imaginary Fashion—dreams of artists, and reprints from Foreign publications—but in that it offers only **Real, Genuine, Decided Fashions**, as accepted and endorsed by the *Elite* of New York City.

Every article—Ladies' and Children's Suits, Fine Under-clothing, Baby Wear, Trimmed Bonnets, Lingerie and Neck Wear, Dress Trimmings, Dress Goods, Jewelry, Gloves, and thousands of other Goods interesting to ladies—each is **richly illustrated**, accurately described, and accompanied by the price at which it can be purchased. Our Magazine, therefore, compares with other Fashion Journals as does a good slice of Pudding with a Cooking Recipe. Other Journals tell you what *can* or *may* be worn. Ours tell you what is *being worn*, and the price at which you can make it up or buy it ready made. We venture to say that more, practical and positive information can be obtained as to New York styles and prices from **one number** of our "Quarterly," than from a **dozen shopping excursions** to New York City.

Interleaved between the Fashions, our "Quarterly" offers also the very best **original Reading Matter**—practical essays on "Cooking," by Miss Corson, Directress of New York Cooking School—charming papers, poems, and stories by "Kate True," "Daisy Eyebright," "Paul Long," "Madge Elliott," "Mrs. Pollard, &c., &c. Instructive Department for Young Folks.

Our enormous Subscription List of last year, and our constant receipt of innumerable complimentary letters, make us believe that our "Quarterly" ought to go to every family in the United States.

Subscription price, 50 cents per year (4 numbers); 15 cents per Number.

Stockbridge Manures

Manure for the Wants of the Crops.

"Do You Feed your Cow as you Feed your Pig?"
Fertilizers should not only be compounded in different proportions, but regard should be paid to the nature of the crops. For example: a different source of nitrogen should be used for some crops than for others, and the same with potash. To mix up a little of this or that in indifferent or hap-hazard proportions is but the crudest way of making a fertilizer, and is generally employed by those who have no refuse material to dispose of. Do you feed your dog as you feed your horse? your cow as you feed your pig? They consume, it is true, the same elements of nutrition, but they require them in different forms. The same is true of plants. Now this difference is recognized to a certain extent in the Stockbridge Manures, and is one of the reasons why they have produced such satisfactory and wonderful results.

THEY SAY:

Providence Co., R. L. Geo. C. Elliott, 1877.—The Stockbridge Manure produced twelve tons hay on five acres land. Worcester Co., Mass., W. J. Wheeler, 1877.—Potatoes yielded per acre on the Stockbridge Manure 175 bushels, smooth and of fine quality.

Cook Co., N. H., John Morse, 1877.—I had Stockbridge Manure for corn, potatoes, and fodder corn, and used it by the side of land with stable manure. The result in all being in favor of the Stockbridge, and the potatoes did not rot as on stable manure.

"There are no potatoes so clean and free from blemish, as those grown with artificial fertilizers."—*Am. Agriculturist.*

Can I Afford to use Fertilizers?

This question is asked by nearly every farmer, and must be answered by each one for himself. It would, however, be more easily answered if farmers knew better what to expect of fertilizers. The Stockbridge Manures are made to furnish the plant-food for so much crop, and before the farmer buys, he is informed as to what he may reasonably expect to obtain under average conditions of soil, season, seed, etc. The results of the last five years have shown that in at least 90 per cent of the trials, the results have been fully equal to those they were lead to expect, and in some cases far better, showing that the application of a certain amount of plant-food to produce certain results is practicable as well as common sense. The Stockbridge Manures, therefore, enable the farmer before buying them, to calculate and settle for himself whether he, under his own peculiar circumstances, can afford to use them or not, which is *not* the case with other fertilizers in common use.

87 Bushels per Acre.—Hampden Co., Mass., William Birnie writes: "I used \$300 worth last year. Results highly satisfactory. Used \$38 to an acre; would not have produced 50 bu. of ears, and it produced 175 bu. of ears—sound corn."

90 Bushels Corn per Acre.—Essex Co., Mass., James P. King, 1877.—I used \$30 worth on one acre of land, and harvested 90 bushels of shelled corn to the acre, no other manure being used. On fodder corn, \$12 worth to the acre, I obtained more weight per acre than with manure at the rate of 4 to 5 cords per acre. I am satisfied as good crops can be obtained by the use of Stockbridge Manures as with stable manure, and at a great saving of labor.

Originated by Prof. STOCKBRIDGE, Professor of Agriculture in the

MASS. AGRICULTURAL COLLEGE.

Our prices will compare favorably with any reliable house in America. All the leading Field, Veg. and Flower Seeds, Agr'l Implements, etc. For elegant illustrated Catalogue, Address BENSON, MAULE & CO., 223 Church St., Philadelphia, Pa.

See advertisement, page 199.

Soluble Pacific Guano.

The Superior excellence of this Guano has been so successfully demonstrated during the past ten years in the Middle and Southern States, on cotton, corn, tobacco, sugar-cane, and garden vegetables—the Company's sales having exceeded the enormous aggregate of 35,000 tons in a single season—that it is now offered for sale with entire confidence as to its merits. No fertilizer ever introduced in this country, has undergone severer tests, or come out of them with its character as a first-class, reliable fertilizer more thoroughly established. In consequence of the satisfactory results of these very complete tests, this Guano has acquired a reputation equal to that formerly enjoyed by Peruvian Guano. It is rich in Bone Phosphate of Lime, finely ground (a large proportion of which is immediately soluble), Ammonia, and Potash, besides other ingredients valuable as plant-food, manufactured at the Company's works, Woods Hole, Mass., and Charleston, S. C., under the supervision of competent chemists.

Troy, N. Y., April 9th, 1878.
NEW YORK FLOW CO., 55 Beekman St., New York.
"Your favor to hand. We don't want any of the Slip Shares among the lot of Points ordered. We fail to see where they benefit any one but the Manufacturer and Farmer. They make more money out of them than out of the ordinary point, and the Farmer can put his Plow in order for about half the expense of buying a new point. We had rather sell a point than a slip." Yours, &c.
We print the above as a specimen of many frank and honest letters that we receive from Dealers. We appeal to the Farmers of the United States to assist us. Not only half the money is saved, but also half the labor, and when ground is dry, even more.

Prout's Hoeing Machine.

Worth double its cost to any farmer for hoeing Tobacco, Cabbage, Corn, or any other hoed crops. Has been in use in the Connecticut Valley for the past three years, and has more friends than any other implement for hoeing by horse-power. For further particulars, send for Illustrated Catalogue to THE BELCHER & TAYLOR AG'L TOOL CO., Chicopee Falls, Mass.

Also Manufacturers of Bullard's Improved Hay Tedders, Feed Cutters, Plows, etc., etc.

Grows WHEAT and GRASS, equal to manure, at Half the Cost, and lasts twice as long.
Farmers!! Send questions on Postal Card to EXCELSIOR FERTILIZER WORKS, Salem, Ohio. Circulars Free.

CLEANING PIPES, DRAINS, &c.

Having had occasion recently to open an obstructed drain, we procured one of Whitman's "Fountain Pumps." We found it very effective; a stream of water being forced from a barrel brought for the purpose, into the drain, clearing it completely in a very short time. The advantage of being able to procure a very considerable pressure, if needed, or to force a continued and rapid stream of water into the drain, is very obvious. Either of these may be done with the "Fountain Pump" better than with any other simple contrivance known to us. If mud or sand has become consolidated in the drain, the stream of water may be thrown into it with sufficient strength to break up the mass and wash it away. It is well to take the precaution in using force to clean a drain or water-pipe, to drive the obstruction back in the way in which it entered the pipe. Water-pipes or waste-pipes in a dwelling, that have become obstructed, may be cleared very rapidly with this force-pump.—*Am. Agriculturist, July, 1877.*

"Adapted To Many Uses."

This pump, owing to its peculiar construction, is adapted to many uses for which an ordinary pump is unavailable. Its mechanism is simple. Vigorously handled the pump will throw a stream fifty feet, making it very useful in cases of sudden fire. Fire Insurance Companies endorse it on this account. It is portable in an unusual degree, as the operator may swing a pailful of water on his arm, and pointing the nozzle in any desired direction distribute water, mixtures, compounds, on trees, flowers, plants, insects, or anything that may require drenching. As an agent for the destruction of the Potato-Beetle and other noxious insects, it is invaluable. The distribution of Paris Green in a water solution is generally coming into favor, as the experience of many farmers, the past summer, was that the poison mixed with flour had a tendency to burn the leaves of the plant. The *Bee Keeper* reports that one of these pumps is a trustworthy agent for controlling bees while in the air, a plentiful spray from a "rose" nozzle causing the bees to come down without ceremony. It is also useful as a syringe for veterinary practice, and as for its household uses they are various, and will suggest themselves to all without prompting.

OXFORD, N. C., Dec. 11, 1878.

We have just had a fire in our town, and used the pump you sent us in June to great advantage. Indeed, we think it would have been a very disastrous fire had it not been for the pump. We think every family in a country village or town should have at least one.—H. C. & W. G. H.

The Ladies Like It,

The Men think It a Good Thing,

And the Children Cry for It,

LEXINGTON, Kentucky, May 31, 1877.

We took the pump along and created some little excitement. The ladies like it, the men think it a good thing, and the children cry for it.—J. W. C. & SONS.

No Dwelling, Country Home or Factory should be without the Fountain Pump. Send for Large Illustrated Circular. J. A.

WHITMAN, Sole Proprietor and Manufacturer, Providence, R. I.

Serviceable Silver-Plated Ware.

"Silver Steel" and "Albata" Silver-Plated.

Save the retailers and jobbers profit, and buy direct of Manufacturers at Wholesale Prices.

An opportunity is now given to buy any of the silver-plated ware manufactured by us direct. The goods are made of good durable metal and will wear for years.

These are not cheap brass goods, like the so-called "Premium Silver Ware," with which the market is flooded, but are warranted as represented. Remember, brass goods are poisonous!

The entire set (50 pieces).....\$11.00

Since our former advertisements appeared, we have decided to give the readers of the *American Agriculturist* a higher grade of goods than those heretofore advertised. Not that the others did not give perfect satisfaction, but we feel that the new designs (made expressly for this trade) will, in quality and finish, be more desirable, and well worth the small advance in price.

All sums over \$1 should be sent in Registered Letter.

W. S. BLUNT'S UNIVERSAL FORCE PUMPS.

Secured by letters patent.

These pumps have enormous power, and are for the house or for out-door wells of any depth. They are constructed with special regard to strength, ease of working, and durability. They can be immediately changed from lift to force pumps, and the air chamber can be revolved, so as to allow the handle to work at any desired angle with the spout. Having close tops, they cannot be tampered with. Attention is called to our new elegant pattern DEEP WELL non-freezing FIRE PUMP. Also, Blunt's Sand Vacuum Chambers.—A complete protection against sand or gritty water in dug or driven wells, pits, mines, and rivers. For hand or steam pumps, all sizes, from 1/4-inch to 4-inch suction pipe.

will make a cord of wood, if it is growing in close timbers, and the limbs are not heavy. If the limbs are large and spreading, such a tree will make $1\frac{1}{4}$ to $1\frac{1}{2}$ cords. A tree one foot in diameter will make only a fourth as much as one twice the diameter. In estimating, it is necessary to remember this fact.

Green Manuring.—"C. E. S.," Lewiston, Me. Plowing in green crops is a good way to begin in renovating a run down farm, but more than that is needed. It is difficult at first to get a heavy crop to plow under, and a light crop does little good. It is best to use some artificial fertilizer, such as Peruvian guano, or the prepared chemical manures, to help the first crop. When land will produce a fair burden of clover, and that is plowed in, a very good beginning is made; but that must be followed by a regular course of manuring and cropping, else the benefit will soon be lost again.

Rotting of Sod.—"R. P. H.," Towah, Wis. Sod from a natural meadow decomposes very slowly, nor do we know of any rapid method of hastening the process, except the addition of plenty of lime. If the partly rotted sods are intended for the fertilizing of light land, we would suggest that they be spread upon the surface now and plowed in as early as possible. They will rot more quickly in that way than any other.

Artificial Fertilizing.—"G. W.," Northampton Co., Pa. We do not doubt that a farm may be very easily carried on with but little live stock and grain sold yearly to pay expenses, by a system of chemical fertilizing, with an occasional green crop plowed in. But the most profitable branch of agriculture is raising live stock, either for meat or dairy purposes, growing grain to feed them, adding some purchased foods, and using some artificial fertilizers to help out what is made on the farm; while the poorest business is growing grain for sale only. Different fertilizers are compounded by the dealers to suit the needs of various crops.

Questions for Discussion.—The Volina (Mich.) Farmers' Club have the following programme of subjects for discussion for the present year, viz.: Breeding and management of hogs; clover and its management; farm stock, kinds, proportions, and management; (a volume might be written on this subject); corn, its varieties and cultivation; sheep shearing, show of stock and implements in May; wheat, varieties and cultivation; Town Fair in October; experience meeting in November; and in December an address by the President.

The Oxford-Down Ram "Freeland."—T. S. Cooper, "Linden Grove," Coopersburg, Pa., writes in regard to the noted Oxford-Down Ram "Freeland" as follows: "In your issue of last November appeared a portrait and sketch of the celebrated Oxford-Down Ram 'Freeland.' Will you kindly allow me to state that 'Freeland' was bred by and belonged to Mr. A. J. Milton Druce, Eynsham, England, who, in 1875, hired him for the season to Mr. John Treadwell for 50 guineas. In 1876 I hired him at public auction from Mr. Druce for 85 guineas, and in 1877 purchased him outright for a long price from that gentleman. He is now at Linden Grove, where I intend he shall end his days. I have forwarded you my Catalogue by this mail, from which you will be able to gather some interesting particulars concerning the breed generally, as well as a history of 'Freeland,' and the number of prizes won by him in England. He has done excellent service in my flock of imported ewes this fall, a number of which I have retained for my own breeding, so convinced am I of the superiority of the breed for general purposes in America. With my Oxford-Downs I won the flock prize of \$100 at St. Louis last fall, a pretty good tribute to the excellence of the breed, and my correspondence has of late been largely increased, owing to the numerous inquiries received respecting them, which also shows their growing popularity. In booking orders for spring lambs I shall soon have reached the length of my tether."

Can Potatoes be Raised Perpetually on the Same Soil?—"F.," Aroostook Co., Me. There is no reason why potatoes should not be grown year after year upon the same soil, if proper fertilizers are supplied. But there is no necessity to do this. Potatoes may be grown once every four years, by making a rotation of grass and clover, potatoes on the sod, and wheat, rye, or other small grain or perhaps a crop of peas, or oats, intervening. On 100 acres there may then be 20 to 25 acres of potatoes yielding \$1,000 each year, which is a handsome money income. Potatoes take from the soil chiefly potash and lime, and if the waste and vines are returned, there is little exhaustion.

The Cultivation of Cranberries.—We hear occasionally of large profits from cranberry culture, but rarely of the losses. That many undertakings in cranberry growing have been altogether the reverse of

profitable, is as true as that many have paid handsome returns. There is no culture which requires such peculiar conditions, and unless these are naturally present, or artificially provided, failure is very sure to follow. Because cranberries often grow wild in abundance, many think they need but little care, while the fact is, their natural localities are of a kind very difficult to imitate. No one should invest money in an attempt to grow this fruit, without first thoroughly understanding its requirements, and making sure that he can meet them. The essentials are: a soil of peat or muck; an abundant supply of sharp sand, without admixture of clay, and water under control. The water system must be so arranged, and the supply sufficient, to allow the meadow to be completely flooded at will, and on the other hand the drainage must be such, that no stagnant water will remain around the roots of the plant, but there must be free drainage to 12 or 18 inches below the surface. Every one of these conditions is essential, and relates to the locality. This will serve as a general answer to the inquiries that come each spring, concerning cranberries. These points, with all other matters in regard to establishing and managing a cranberry meadow, are given in full detail in "Cranberry Culture," by J. J. White, a practical New Jersey grower, which is a remarkably complete work on a special culture, and should be thoroughly studied by every one who proposes to undertake cranberry growing. Like other practical and impartial works, a part of its usefulness consists in showing the folly of attempting the culture unless all the conditions may be met. Sent post-paid by Orange Judd Company, for \$1.25

Glasnevin.—A friend kindly calls our attention to the fact that last month we inadvertently, not ignorantly, wrote Scotland, instead of Ireland, in speaking of a well known Botanic Garden near Dublin.

Effect of Ashes—Salt.—"E. D. S.," Orleans Co., N. Y. 20 bushels of ashes per acre drilled in with grain, would almost certainly destroy the seed, or at least the tender sprout when it germinates. Ashes are always best scattered upon the surface. As ashes are not so quickly soluble as most commercial fertilizers, a larger quantity needs to be used, and as they dissolve slowly, the effect is more permanent. Salt is used as a fertilizer at the rate of 1 to 5 bushels per acre.

Sheep Shears.—"G. B. S.," Cooper Co., Mo. After having tried several so-called improved sheep shears, we prefer the common kind. Those with teeth, or guards, to protect the sheep, give no protection in unskilled hands, and they gun up so much that the work is very tiresome to the wrist and arm. If there is a better shears than the common one, we want to find it.

Flat Cultivation of Corn.—"G. W. W.," Memphis, Tenn. The flat cultivation of corn is generally considered preferable to hilling or plowing up to the rows. We have practised the method for some years, and prefer it to plowing up ridges or hills. Planting in drills is not only more convenient, but there can be more corn grown upon the same ground than when in hills or squares, and the cultivation on the flat will be found cheaper, and, if properly done, equally cleanly.

Trouble With Field Mice.—A note from Coles Co., Ill., states that the district is over-run with field mice, to the great loss of the crops. How many boys are there in Coles Co. of the age of 12—indeed how many men "big enough, old enough, and ought to know better," who will not go out of their way to kill everything in the shape of a snake—for no other reason than it is a snake, and consequently no business to live? The harmless reptile is, in reality, fulfilling the object of its existence quite as well—to say the least, as the boy or man who kills it. How many boys (or males big enough to be men), who own, or can borrow a gun, will not shoot at, or indeed, spend half a day in hunting every little owl, or Sparrow-hawk, or Mouse-hawk? The last of these lives almost solely on field mice, which also form the principal food of most of the smaller birds of prey. If we will persist in killing, or in allowing to be killed, the insect-eating birds, we must expect insects to increase. If we will destroy or drive away the birds and snakes provided to keep field mice in check, we must kill the mice ourselves, or suffer the loss of our crops.

Catalogues Received.

Generally the list of Nurserymen's, Florists, and Seedsmen's catalogues ceases with April, and is not resumed until the announcements for the fall trade come to hand, but here are several that have been belated or omitted from one cause and another. Very full lists will be found in our issues for March and April.

NURSERYMEN.

A. HANCE & SON, Red Bank, N. J., send special list of a surplus stock, and one describing the Honeywell Peach,

YORKUM & Co., Larissa, Cherokee Co., Texas. It will do our Texas friends little good to notice this catalogue now, but we would call attention to an excellent feature in it. For each kind of fruit they give a "Superlative List" of varieties thoroughly tested and commended for Texas, and besides a "General List."

SEEDSMEN.

B. K. BLISS & SONS, No. 34 Barclay St., N. Y.—An extra catalogue, which should have reached us last month. It contains important novelties in field seeds (including potatoes), vegetable and flower seeds; abundantly and handsomely illustrated.

CROSMAN BROTHERS, Rochester, N. Y.—The catalogue of this long-established house is as full and as neat as usual, and we fear that it is our own fault that it was not noticed last month.

C. H. HOVEY & Co., 22 Tremont St., Boston, Mass., besides the catalogue of plants, noted in March, send another of seeds and plants, compact and comprehensive.

E. L. MEYER, "Druggist and Seedsman," Hutchinson, Kas., a full, useful catalogue of garden and farm seeds.

FLORISTS.

GREENBROOK AND PATERSON NURSERIES, J. Grieves, Sec., Paterson, N. J.—Very full in the way of description and cultural directions, mostly for greenhouse stock.

LONG BROTHERS, Buffalo, N. Y., send their list of Dollar Collections, of which there are 30, and very cheap they are. Besides this, they send their general catalogue of plants, very neat and compact, with a list of seeds.

J. WARREN MERRILL, Cambridge, Mass., makes a specialty of native and exotic Ferns; his list is very full; those desiring to exchange or purchase, may address his gardener, A. B. Gilbert, Cambridgeport, Mass.

AGRICULTURAL AND HORTICULTURAL MACHINERY AND APPLIANCES.

ADRIANCE PLATT & Co., No. 165 Greenwich St., N. Y., send two publications relating to the "Buckeye" Mower and Reaper. The same perfection attends these publications that characterises the machines they describe. One illustrates the mowers and reapers at work and on the road, and each picture is a work of art. The horses are at work, the men are driving, and there are no "lay figures." The other gives every extra part to each machine, from the driving-wheel down to the smallest screw, showing a wonderful attention to details, and making a work valuable to every owner of a "Buckeye."

THE BEECHER BASKET CO., Westville, Conn.—An illustrated catalogue of their well known baskets and crates.

THE BELCHER TAYLOR & Co., Tool Co., Chicopee Falls, Mass.—Full illustrated catalogues of the "Bullard Hay Tedder," and "Proust's Hoeing Machine," both of excellent reputation.

BOOMER & BOSCHERT, Syracuse, N. Y.—We described their remarkable cider and wine Press, as seen at the Centennial, in the *American Agriculturist* for July, 1877. This fully illustrated catalogue gives every detail.

WM. L. BOYER & Co., Philadelphia, Pa., Farm grist mills for grinding all sorts of grain; fodder-cutters and a clover-seed gatherer which harvests one acre per hour.

GARDNER B. WEEKS, Syracuse, N. Y., Dairy Apparatus and supplies, including steam-boilers and engines.

H. B. GRIFFING, 60 Cortlandt St., N. Y., all sorts of machinery, fertilizers, and tools for the farm; including the popular Kirby mower and reaper, with hay and straw-presses, and the new manure-hauling press. Also city stable manure put up in small bales of 300 lbs. each.

HUBBELL & CHEESEBORO, Geddes, N. Y.—A stone-ware package, glazed inside and out, for butter.

JOHN L. KIPP, No. 163 Eldridge St., N. Y.—A catalogue of the wares made at the "Kipp Wagon Works," including carts and trucks, hand-carts and wheel-barrows in an astonishing variety, each style illustrated.

NEW YORK PLOW CO., Beckman St., N. Y., make the Nishwitz Harrow, the Adamant Plow, and various other improved farm machines.

N. PAGE, JR., Wakefield, Mass., continues to make his Pump and Sprinkler, illustrating it in two catalogues.

B. W. PAYNE & SONS, Corning, Steuben Co., N. Y.—An illustrated catalogue of the various forms of portable and stationary steam-engines made by them.

RUNSEY & Co., Seneca Falls, N. Y.—This catalogue, of 160 large pages, might well be called an illustrated treatise on Hydraulics. Almost everything contrived for raising water, from the simplest Pitcher Pump, through all sorts of force, hand and steam pumps and Water Rams, up to the large Fire Engine, including every possible accessory, from a screw, up to the trumpet of the Captain of the "masheen," is here given in full.

THE YALE VERTICAL GRIST MILL, made by the Yale Iron Works, New Haven, Ct., also engines for small boats and yachts, lathes and other machinery.

J. R. WHITTEMORE, Chicopee Falls, makes, and Whittemore Brothers, Boston, also sell, the Victor Feed Cutter and the Champion Horse Rake, of which they send illustrated descriptions.

J. C. WOOD & BROTHER, Fishkill, N. Y., send an illustrated catalogue of berry baskets, crates, and other fruit packages, including the small peach basket which we introduced to Eastern fruit dealers a few years ago.

LIVE STOCK.

HERBERT MERRIAM, Cherry Brook Farm, Weston, Mass., Ayrshire cattle; Yorkshire and Berkshire pigs.

BELLEVUE STOCK FARM, Dundee, N. Y. Celebrated Stallions for the season of 1878. Details are furnished by N. Powlison, Supt. of the farm.

EDWARD LUTZ, 80 5th Avenue, Pittsburg, Pa., Brown Leghorn fowls.

J. H. MORRISON, Marlow, Cheshire Co., N. H., Plymouth Rock fowls.

MISCELLANEOUS.

AGRICULTURAL INSURANCE CO., Watertown, N. Y.—Insures only farm property and private residences. They

describe their business, and give figures in a neat circular. J. S. BACH & CO., 38 Dey St., N. Y., illustrate in a neat pamphlet a wonderful variety of their self-adjusting watch keys, and other specialties.

W. H. CUMMINS, Milford, Conn., sends catalogue of his Plymouth Rock fowls.

J. A. PARK & Co., Lansing, Mich.—Illustrate and describe their "Harvard and Yale" Chair Desks.

L. C. Root, Mohawk, N. Y.—Bees; things to keep them, and to smoke them out, Honey Extractors, and all such "apiarian notions."

L. H. RUSSELL, Stratford, Conn.—Scroll saws, materials and patterns in endless variety.

GEO. W. SIMMONS, Newark, Del.—Hives of various kinds and apiarian supplies in general.

ERNEST STEIGER, 22 and 24 Frankfurt St.—German books of all kinds, kindergarten literature, scientific periodicals, and various special catalogues.

OSCAR W. YOUNG, 60 4th St., Brooklyn, N. Y.—A priced and numbered catalogue of the beautiful scrap-book figures, to which we referred some months ago.

ADRIANCE REAPER AT WORK.

ADRIANCE PLATT & CO.,

Manufacturers of Buckeye Mowers and Reapers, and the Adriance Reaper,
165 Greenwich St. (near Courtlandt St.), N. Y. Manufactory, Poughkeepsie, N. Y.

The ADRIANCE is a light, strong, simple, efficient REAPER, which will work well in all kinds and conditions of grain, and combines more good points than can be found in any other. It has a folding platform, and is in all respects worthy to rank with the Buckeye Mower.

The BUCKEYE has for 21 years held its position as the LEADING MOWER and REAPER of THE WORLD, because it is superior to all others in the principles of its construction. It is the only machine which has given entire satisfaction to the farmer; its AVERAGE DURABILITY has been MORE THAN DOUBLE that of others, and the COST OF KEEPING IT IN REPAIR LESS THAN ONE-HALF.—Prices Reduced to the lowest point at which the high standard of excellence in material and workmanship can be maintained. Descriptive Circulars forwarded by mail.

GRANT'S EXCELSIOR HAY FORK.

Patented April 2, 1877, by PETER GRANT, of Clinton, Ontario.

We are manufacturing and introducing to the agricultural community the above new and improved invention.

For Unloading Hay, Straw, &c.

We claim that, for completeness of design, simplicity of construction, ease of operation, strength of parts, and durability of wear, it rivals the world.

It was awarded the only Medal with a Commendatory Report of the Judges at the Centennial Exhibition, held in Philadelphia 1876, over 36 Competitors.

Correspondence is solicited in regard to State and County Rights, and Agencies in all parts of the country, or orders for the Forks.

Price of single fork, \$12.00.

For particulars address

PETER GRANT & CO.,
Concordville, Del. Co., Pa.

RAILWAY PITCHING APPARATUS.

Chapman's. Best Fork and Conveyor in use. Unloads and carries Hay, Grains, &c., over deep mows, into sheds, barns, &c. Saves labor, time, money. Sent on trial. Circulars sent. Agents wanted.

G. B. Weeks Syracuse, N. Y.

Use the Anti-Friction Hay-Carrier.

For elevating and conveying Hay, Grain, etc., in barn, har-rack, shed, or field. It elevates perpendicularly and conveys horizontally any desired distance. No trouble about getting over high beams and to the end of deep mows, or to the top of high stacks. **Thousands are now in use.** Five tons have been stacked and the frame moved in 45 consecutive minutes. Fifty tons have been stacked in a single day with this Frame and Carrier. Send for Circular "2" to **U. S. WIND ENGINE & PUMP CO.,** Batavia, Ill.

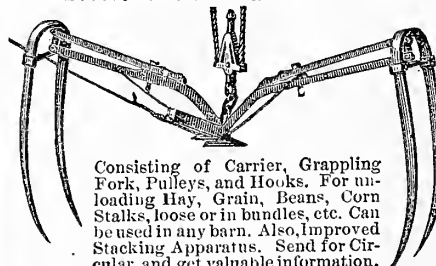

FOUST'S

HAY LOADER.

A perfect machine for rapidly pitching hay, barley, and all loose grain on the wagon in the field. Saves as much time and money as the mower and horse rake. Thousands in use by the best farmers in the country. Price reduced. Send for Circulars to the manufacturers, **STRATTON & CULLUM,** Meadville, Pa.

GARDNER'S RAILWAY PITCHING APPARATUS.

THE ORIGINAL & ONLY GENUINE
"Vibrator" Threshers,
 WITH IMPROVED
MOUNTED HORSE POWERS,
 And Steam Thresher Engines,
 Made only by
NICHOLS, SHEPARD & CO.,
 BATTLE CREEK, MICH.

THE Matchless Grain-Saving, Time-Saving, and Money-Saving Threshers of this day and generation. Beyond all Rivalry for Rapid Work, Perfect Cleaning, and for Saving Grain from Wastage.

GRAIN Raisers will not Submit to the enormous wastage of Grain and the interior work done by the other machines, when once posted on the difference.

THE ENTIRE Threshing Expenses (and often 3 to 5 Times that amount) can be made by the Extra Grain SAVED by these Improved Machines.

NO Revolving Shafts Inside the Separator. Entirely free from Beaters, Pickers, Rubbers, and all such time-wasting and grain-wasting complications. Perfectly adapted to all Kinds and Conditions of Grain, Wet or Dry, Long or Short, Headed or Bound.

NOT only Vastly Superior for Wheat, Oats, Barley, Rye, and like Grains, but the ONLY Successful Thresher in Flax, Timothy, Millet, Clover, and like Seeds. Requires no "attachments" or "rebuilding" to change from Grain to Seeds.

MARVELOUS for Simplicity of Parts, using less than one-half than usual Belts and Gears. Makes no Litterings or Scatterings.

FOUR Sizes of Separators Made, ranging from Six to Twelve Horse size, and two styles of Mounted Horse Powers to match.

STEAM Power Threshers a Specialty. A special size Separator made expressly for Steam Power.

OUR Unrivalled Steam Thresher Engines, with Valuable Improvements and Distinctive Features, far beyond any other make or kind.

IN Thorough Workmanship, Elegant Finish, Perfection of Parts, Completeness of Equipment, etc., our "Vibrator" Thresher Outfits are incomparable.

FOR Particulars, call on our Dealers or write to us for Illustrated Circular, which we mail free.

THE UNION RAILWAY

HORSE POWER & Premium Thresher. This power produces much more power than other railway powers, with much less elevation.

Send for Description Circular.

W. L. Boyer & Bro., 2101 Germantown Ave. Phila., Pa.

La Dows Jointed Pulverizing & Smoothing DISC HARROW.

Being jointed in the center, is adapted to both smooth and uneven surfaces. Acknowledged the best of the kind, and will pulverize and cover seed better in one operation, than going over twice with others. Made with both Chilled Metal and Cast Steel Discs polished. Send for circular and price list. Manufactured by **WHEELER & MELICK CO.,** Albany, N. Y., for the United States, except New England. **EVERETT & SMALL,** Boston, Mass., Manufacturers for the New England States.

THE WESTINGHOUSE THRESHING MACHINES & HORSE POWERS

Threshers for all sizes of Horse Powers and Steam, Lever Powers for 4 to 10 Horse, and Endless Chain Powers for 2 and 3 Horses—and Engines from 4 to 10 Horse Power. All with late and important improvements. Send for Circular. **G. WESTINGHOUSE & CO.,** Schenectady, N. Y.

MEDAL MACHINES.

First Premiums at all Competitive Trials. Railway, Chain and Lever Horse Powers, Threshers and Cleaners, Threshers and Shakers, Clover Hullers, Feed Cutters, Wheel Horse Rakes, Horse Pitchforks, Shingle Machines, Straw Preserving Rye Threshers, Portable Steam-Engines, Cider and Wine-Mills and Presses, Dog and Pony Powers, etc., etc.
WHEELER & MELICK CO.,
ALBANY, N. Y.
 Send stamp for Circular and report of Centennial trial.

The Birdsell Clover Separator,

SOUTH BEND, IND.
FOR SALE.
A VALUABLE DAIRY FARM of about 300 acres, buildings, water, &c. all in best condition. \$100 worth of milk at wholesale is now sold monthly. Will be sold cheap. For particulars address **WM. LINCOLN & CO.,** Warren, Mass.

Cotton Seed Huller AND FEED-MILL COMBINED. For Plantations and Oil-Mills. Used by Planters, the Oil-Mills in New Orleans and through the country. Send for Circulars and Judges Report. Pay for itself in a few weeks. **D. KAHNWEILER,** 120 Centre St., New York.

THE GLOBE NAIL. THE BEST HORSE SHOE NAIL EVER MADE.

About ten years ago the **GLOBE NAIL COMPANY** of Boston, put on the market the first pointed, polished and finished Horse Shoe Nails ready for driving. Previous to that time all Horse Shoe Nails were pointed, and most of them made, by the shoers in their own shops at the rate of but six pounds per day.

The **Globe Nail** was at once found to be much cheaper and better than any then in use. It soon became so popular that all manufacturers of Horse Shoe Nails were compelled to make their Nails to resemble the **Globe**. For the last ten years it has been the model. Each year the Nail has been greatly improved in quality, and to such a point have we educated the shoers that now they will hardly use a nail unless it is absolutely perfect.

600 lbs. Finished Nails per day.

At the Centennial Exposition in Philadelphia, we were awarded the Medal and the following report, far stronger than that given upon any other Nail:

INTERNATIONAL EXHIBITION, 1876.
U. S. CENTENNIAL COMMISSION.

[BUREAU OF AWARDS.]

PHILADELPHIA, June 22, 1876.
No. 239, *Globe Nail Co., Boston, Mass.*

Horse Shoe Nails, Pointed, Polished and Finished. The uniformity in size, smoothness of finish, hardness and tenacity of the iron, closeness of fibre, and excellence of the head and point, the tensile strength of body, and riveting properties of these Nails, unite in making them of the very highest class of manufacture.

Recommended for an Award of Merit.
DANIEL STEINMETZ, Phila., Chairman,
J. D. IMBODEN, Richmond, Va.,
CHARLES STAPLES, Portland, Me.,
G. L. REED, Cherfield, Pa.,
DAV. McHARDY, Aberdeen, Scotland,

We annex a sample of the testimonials we receive daily from all parts of the country:

ST. LOUIS, Mo., June 8, 1877.
GLOBE NAIL CO., BOSTON, MASS.
Gentlemen: Find enclosed advertisement and postal card concerning your Nail. [Referring to a scurrilous advertisement and postal card, disparaging the **Globe Nail**, circulated by a rival manufacturer over the humbug signature of "Humane Society for the Prevention of Cruelty to Animals." No Society bearing that title ever existed.] As I take a great interest in the prevention of cruelty to animals,—horses in particular,—I desire to say a few words in favor of **The Globe Nail**. Though I am not a very extensive Horse Shoer, yet I have used enough Nails of the different makes to speak knowingly. I have used the **Globe Nail** in my shop and on the race track for six years, on all classes of horses, from the heavy draft horse to the tender footed running horse; and I can safely say it has no superior in point of Toughness, Shape, and Finish, if it has any equal. I have used about fifteen hundred pounds of **Globe Nails** a year for the last six years, and in that time I have found four imperfect Nails, two of which I returned to you about two years ago and received in return four perfect ones, for which accept my thanks. If my men had no better sense than to drive those imperfect Nails in a horse's foot, I would not consider it the fault of the Nail if the horse was lamed. If bosses would look more to the competency of their men and less to trying to get shoeing nails a few cents a pound cheaper, we would have fewer lame horses. I know for safety and durability, with a man who understands his business to drive them, your Nails can't be beat! I am willing to pay, without any suit, for all horses that are lamed in my shop by using the **Globe Nail**. As long as it is made as at present, I shall continue to use it, even if I could get other Nails for nothing. I consider it the safest Nail that was ever driven in a horse's foot.

Yours Very Respectfully,

(Signed,) P. H. O'NEILL,
Horse Shoer, No. 1007 Broadway.

P. S.—I think I could get every boss in St. Louis to sign this if I thought it necessary.

The best Horse is sure to win. SO
CLEAR THE TRACK FOR THE
GLOBE NAIL CO.

BUTTER WORKER.

The most effective, simple and convenient yet invented. Works 30 lbs. in less than 5 minutes, thoroughly working out buttermilk and mixing the salt. AGENTS WANTED. Send for circular.

A. H. REID,
6 N. Eighteenth St., Philadelphia Pa.

BENSEL'S PATENT BUTTER COOLER.

The best and most convenient refrigerator ever invented, being made of porous unglazed earthenware, and is both simple, durable, and cheap. It operates without cost, using only water, and is specially adapted for warm climates. Sample boxed and sent by express on receipt of \$1.00. For circular and further information address

"GET THE BEST."

HIGHEST AWARD at the CENTENNIAL.

Cheap, because so well made, durable, and efficient. Nine sizes made, churning from one to 150 gallons. Warranted to be exactly as represented. Sold by all dealers in really first class Farm Machinery.
PORTER BLANCHARD'S SONS, Concord, N. H., Sole Manufacturers. Send for Circulars.

The Rectangular Churn.

Simple, efficient, and always reliable. No inside fixtures. Fifty per cent in labor saved over any other churn. Five sizes made. The Highest award given over all competitors at the late Dairy fair in Chicago. An energetic man wanted in every town, to act as agent. On churn sent at wholesale price, we have no agents.
CORNISH & CURTIS,
Fort Atkinson, Wis.

THE LILY BUTTER-WORKER

We guarantee it the best and cheapest Machine in the world. No hard labor. Mixes the salt thoroughly, and takes all the milk out, with five to ten minutes work. Circulars sent on receipt of stamp.

HENDERSON & CO.,
316 Race St., Phila., Pa.

WILLIAM CROZIER has much pleasure in calling the attention of Cow-keepers, Farmers, and Dairy-men to the **NEW SELF-MILKING APPARATUS**. This Apparatus or Cow Milker, has been tested by a large number of practical Agriculturists, Dairy-men, &c.; and, without exception, merited high encomiums and commendations, for its adaptability and wonderful rapidity in the Milking of Cows. It is considered one of the most invaluable and useful Machines yet invented.

Amongst its many advantages are—
1st—It is SELF-ACTING, easy of application; and can be used by any person, however ignorant of Milking.
2nd—It will Milk any Cow in FOUR Minutes effectually, and its use is more agreeable to the Cow than Hand-Milking.
3rd—It is a great boon in the case of Sore or Corded Teats.
4th—Its Usefulness, Simplicity, Saving of Time, Cleanliness, Durability, and Cheapness, prove it to be a most important and necessary adjunct to a Dairy, and it has only to become better known to be universally used.
Sent free on receipt of Post Office order for \$5.
Printed Instructions accompany each Machine.

MILK TUBS.

COW-KEEPERS should not be without one of these, as they are invaluable for sore or Corded Teats.

PRICE \$1.00 each.

WM. CROZIER, Northport, L. I., N. Y.

Improved Butter Tubs and Coolers,

with movable Ice Chambers. Best in the market. Are made in 12 different sizes, of white Cedar, bound with galvanized iron or brass hoops. Within the tub is fitted a tin Cooler, having a movable Chamber for ice at each end. On the tin is constructed a series of ledges, on which rest the shelves for supporting the butter; suitable for round, half-round, and square prints or rolls. Can be locked for shipping. Will keep butter in good order from 18 to 24 hours. Capacity from 12 to 300 lbs. Price from \$3 to \$25.
J. G. KOEHLER, Manufacturer,
503 North 2nd St., Philadelphia, Pa.

Agricultural Insurance Company, of Watertown, N. Y.

Capital \$200,000.00. Net Surplus, \$201,329.97. Total assets for the security of Policy holders, January 1st, 1878, \$1,053,137.60. Insures only Farm Property and Residences against fire and lightning. Takes no business risks.

GOOD MEN WANTED

to sell the celebrated cow feller. It sells on sight. Warranted to make the worst kicking cow gentle to milk, in three days. There is nothing equal to it for breaking bellers. Retail price \$2. For further information send for illustrated circular to

MRS. OLD FOGY DOES
NOT USE THE
ROBBINS WASHER.

MRS. COMMON SENSE
DOES.
TAKE YOUR CHOICE.

TO MAKE MONEY SECURE AN AGENCY

FOR THE

CELEBRATED

ROBBINS FAMILY WASHER.

This machine has been ON TRIAL for the past six months in every State and Territory in the Union, and the almost unanimous verdict of housekeepers is this: "Your Washer has proved a complete success." Some of the reasons why this popular verdict has been reached may be found in these facts:

The Robbins Washer is an entirely NEW MACHINE. It is constructed upon a NEW PRINCIPLE—that of forcing water by downward pressure through the fabric. The dirt or discoloration is removed by water force—there is no rubbing or friction about it. This principle is the only one that has ever been successfully applied to the cleaning of fabrics by machinery. All others have failed in one or more essential points. The Robbins Washer will cleanse perfectly, without rubbing, all kinds of wearing apparel, table or bed linen. It will not injure the most delicate fabric. It is the greatest bleacher extant, and for this purpose alone is worth ten times the price of the machine. It is simple, self-operating, never gets out of order, and will last a lifetime. It saves time; it saves labor; it saves material.

By purchasing a ROBBINS WASHER you can count the hard drudgery of the washboard among the things of the past.

Therefore, we confidently say to every housekeeper in the land, You want a ROBBINS WASHER. You cannot afford to be without one. It will pay to buy one.

THE RETAIL PRICE IS ONLY \$3.50.

Sample to those desiring agencies, \$3.

In bringing the Robbins Washer before the public it becomes necessary to take into brief consideration the

ART OF CLEANSING FABRICS,

which, although so common, is yet imperfectly understood. Having had a lifelong experience in the laundry business—in connection with first-class hotels, public laundries, asylums, hospitals, &c.—we know whereof we speak. The numerous devices of friction rollers, pounders, squeezers, dashers, agitators, steam wash boilers, &c., have all done very well, so far as it was possible for such principles and devices to do. But they have all failed in one or more of the three essential points, viz: The saving of labor, the wear and tear of clothes, or in perfectly extracting the dirt or discoloration—all of which are accomplished by the ROBBINS LITTLE WASHER.

WHAT IS IT THAT REMOVES THE DIRT?

You may ask all washerwomen and housekeepers, and your answer from nine out of ten will be: "Plenty of elbow grease," or, in other words, plenty of hard, laborious rubbing on the washboard. And such is the case, for you first have to rub soap upon the cloth, then you have to rub it in to make the dirt soluble. But does that remove it? No; to do that, so far as it was possible for such principles and devices to do. But they have all failed in one or more of the three essential points, viz: The saving of labor, the wear and tear of clothes, or in perfectly extracting the dirt or discoloration—all of which are accomplished by the ROBBINS LITTLE WASHER.

The way in which this could be the most economically accomplished is what we have so long and patiently sought after, and at last a principle has been demonstrated that in unting all the above named, in

THE PRINCIPLE OF THE LITTLE WASHER

is embodied all the essential points. First, we have the desired heat, which expands the fabric and causes it to discharge the dirt. Second, we obtain a powerful suction beneath the clothes, which causes a rapid downward current of water force through and through them, thereby removing the dirt. Third, we use a body of water, which holds the dirt in solution. Thus we cleanse thoroughly, rinsing the clothes as usual being all that is required to complete the operation.

The Washer is composed of solid galvanized iron, which will not rust or corrode. There are two sizes—the No. 1, or family size, for ordinary household use; and No. 2, or hotel size, suitable for country hotels, boarding-houses, laundries, &c.

OUR METHOD OF HANDLING.

We want agents everywhere throughout the United States, in every State, county, town, and hamlet. The retail price of No. 1 Washer is \$3.50; of No. 2 Washer, \$5. But we sell sample machines of No. 1 size at \$3; No. 2, or small hotel size, at \$4. Canvassers for this Washer can make more money with it than with anything ever before offered to the public. As, for instance, we established two agencies to test the sale of the Washer upon its merits—one in Naugatuck, Conn., and one in Providence, R. I. The former, Mr. Charles Daniels, in a town of about 2,000 inhabitants, sold by canvassing in two weeks eighty-two Washers. In the latter place Mr. James Roberts, now of Naugatuck, Conn., sold in less than three months, without canvassing or advertising outside the store, over 500 Washers. A thing never before heard of.

TO PERSONS OUT OF EMPLOYMENT

we would say, if you want to secure a paying business, now is your time. Don't wait till the best territory is taken up, but send at once for sample machine and go to work. By following instructions you can sell to nearly every family in your neighborhood. Others have done it, and there is no reason why you should not. Full directions and instructions accompany each machine. Also, special terms to agents, circulars, testimonials, &c.

All orders must be accompanied with cash.

Remit by money order or registered letter to

NEW YORK
AND BY TOY DEALERS GENERALLY.

The NEW CHAMPION Mower.

Embodies many New and Valuable Features never before combined in Mowers or Reapers.

This peculiar Machine is unlike any other ever made, and is a new departure in the construction and mode of operating Mowing Machines.

The draft is light; in operation it is *nearly noiseless*; and its adaptation to various kinds of work most extraordinary. The operator has the most **PERFECT CONTROL** of the machine when at work. *The knife will run at any angle, and in any position in which it can be placed.* The machine will work with equal facility over stones, stumps, among trees, on heavy hill-sides, through gullies, over ridges, in swampy marsh and over bog; in the shortest and down grass, whether laying to or from the machine, and in the **TALLEST CROP** to be cut. The machine can be instantly adjusted while in operation to cut low, to take up lodged and very short grass, or to cut over rough ground, wherever it is desirable to cut the crop high; and *both ends of the cutting apparatus may be carried entirely above the ground, at any distance, FROM AN INCH TO ONE FOOT.* The bar may

be lifted to an upright position to pass a tree, remove any lodgment, or to free the guards.

The machine can be **INSTANTLY THROWN OUT OF GEAR** and can be put into working order in a moment's time, and without the operator leaving his seat or stopping the team. **THE WHEELS ARE WIDE APART**, to stride the swath, and leave the grass unmolested. The steady, uniform, and powerful movement of the knife is the crowning feature of success. There are but two small cog-wheels in the machine, and they are about the size of a dinner plate. There is no Pitman and no gearing in the drive-wheels. The gearing is enclosed by one small disk or rim, perfectly protecting it from dirt. One of the great features of this machine is discarding the old style of quick running gearing, and consequently dispensing with the frame work, heretofore employed to carry the gearing.

WELL DESERVED AND CONVINCING TESTIMONY.

THE NEW CHAMPION never received a faint-hearted endorsement. We present a few tersely stated commendations:

"I cut over 100 acres of hay and grain one season, and it did its work perfectly."—J. SHELL, Evans Mills, N. J.

"I value the Noiseless Action, and its reliability in hard-cutting, among its highest qualifications."—J. COGGESHALL, Middletown, R. I.

"It is a powerful cutter, very light draft, durable, and completely under the control of the driver."—TIMOTHY S. FORD, Lowell, Mass.

"It cuts through thick and thin; does not choke."—D. HODGES, Lawn Ridge, Ill.

"The new movement is the longest stride ever taken in Mowing Machine Improvements."—G. L. GOODRICH, Newburyport, Mass.

"It works like a charm. It is the most complete and perfect machine I ever saw."—THOMAS MONTEITH, Monteith, Mich.

"As to easy draft it can not be beat. I used but one horse on a two-horse machine."—S. N. SANDERS, North Sudbury.

"It excels all machines in use at present."—HENRY D. B. FREER, Gardner, N. Y.

"I did not have to throw the machine out of gear, or stop the team to pass a tree."—ALBERT GRAHAM, Johnson's, N. Y.

"I would not exchange it for any other, and its price added."—JOHN B. PALMER, Wilton, Maine.

"It cuts where other mowers failed. I regard it as ahead of all machines I ever saw."—JAMES H. THOMPSON, Bushwell, Ill.

"What puzzles us is to find out what makes it run with so much ease, and where it gets its power."—J. T. & J. A. DRONENBURG, Frederick, Md.

"I have cut among stumps, and over gutters, without injuring the machine in the least."—R. B. WILLIAMS, Hazlettville, Del.

"Farmers, when you try it, you will buy no other."—D. SHOOK, Rhinebeck, N. Y.

"I have used a mower (with this movement) four seasons, and the extent of cash out for repairs has been *sixty-two cents*."—E. F. MAYO, Warwick, Mass.

"The New Champion is equal to any emergency. I have given it a severe test. No lost motion, and no perceptible wear."—MILTON DANCE, Long Green, Md.

"A man will never want but one of these machines, for it will last a life-time."—GEO. W. HARRINGTON, Plainville, Mass.

There was no special effort made during the last Fair season to secure awards of Premium for the New CHAMPION MOWER. But wherever it was convenient for our agents to exhibit it they did so always, however, for the purpose of presenting it to the attention of farmers, rather than for that of competing for the premiums. Yet it bore away from every Fair and Agricultural Exhibition at which it was present, with only one or two exceptions, the **FIRST HONORS—THE RED RIBBONS.**

The Champion Reapers and Mowers, (including **THE NEW CHAMPION MOWER**), are manufactured by Whiteley, Fassler & Kelly, Springfield, O., for the Eastern portion of the U. S.; by the Champion Machine Company, of Springfield, O., for the Southern and South-western portion of the U. S.; by Warder, Mitchell & Co., Springfield, O., for the Northern, and North-western portion of the U. S.; by the Toronto Reaper and Mower Company, for the Dominion of Canada. Sold by L. H. Lee & Bro., Baltimore, Md.; Whiteley, Fassler & Kelly, Schenectady, N. AMERICAN

AGRICULTURIST

FOR THE FARM, GARDEN & HOUSEHOLD.

VOL. XXXVII.

NUMBER 6.

PUBLISHED BY THE
ORANGE JUDD COMPANY,
245 BROADWAY,
NEW-YORK.

Peter Henderson's Books.

Read what practical people say, who know what books they need, and who also know when they get such books. The following extracts are taken from letters, of which very many have been received, giving testimony to the value of the works mentioned. No better books, or those more practically useful, have ever been published upon the subjects of which they respectively treat.

GARDENING FOR PROFIT.

Price, post-paid, \$1.50.

EXTRACTS FROM LETTERS.

"By following the plain directions given in your books, 'Gardening for Profit,' and 'Practical Floriculture,' I have got into a good paying business, having succeeded far beyond my most sanguine expectations, both with vegetables and flowers.

Feb. 2, 1877. ALBERT WILLIAMS, Sharon, Pa."

"Your work, 'Gardening for Profit,' is to all other similar works, what Blackstone is to all other law books.

Jan. 16, 1878. JOHN T. CRIST, Independence, Mo."

"I have both your works, 'Gardening for Profit,' and 'Practical Floriculture.' I have been repaid a hundred times for the money they cost.

Sept. 8, 1876. M. E. LEA, Brighton, Maryland."

"'Gardening for Profit,' if valuable to American gardeners, must be indispensable to foreigners, as all know the mistakes likely to be made, which your instructions show so well how to avoid.

Aug. 29, 1876. JOHN MASSEY, Batavia, Ill."

"You have raised up a good many enemies among our old market gardeners, who say you have exposed all the secrets of the trade, in your 'Gardening for Profit,' but you have made a life-long friend of me, for by reading your book, I have made my business, of market gardening, pay, which I never had done before.

Oct. 20, 1877. AARON WILLIS, Newark, N. J."

"In 1870 I purchased your book, 'Gardening for Profit,' and turned about five acres of my farm into vegetables for our market here, and with such success, that the profits from those five acres have been more, annually, than that of my whole farm of 150 acres.

Dec. 3, 1876. HENRY G. STEWART, Buffalo, N. Y."

"Your suggestions in 'Gardening for Profit,' induced me to try raising vegetables here for northern markets, and though prices have been unusually low for the past two seasons, yet I think I can now see my way clear to a very profitable trade.

Jan. 10, 1877. MICHAEL SHANNON, Norfolk, Va."

GARDENING FOR PLEASURE.

Price, post-paid, \$1.50.

EXTRACTS FROM LETTERS.

"Your books on horticulture have been of great value to me, the article on Strawberry Culture, in 'Gardening for Pleasure,' alone, has been to me worth ten times its cost this season.

July 2, 1877. GEO. I. SREATOR, Garrettsville, Ohio."

"Your work, 'Gardening for Pleasure,' contains more plain, practical information than anything I ever read on the subject—and I know of what I speak, having been gardening for 30 years.

Jan. 23, 1877. A. C. LANIER, Madison, Ind."

"Send me your 'Gardening for Pleasure.' I have both of your other works, and would not otherwise replace them.

March 5, 1877. LOUIS SIEGLER, Harrisburg, Pa."

"'Gardening for Pleasure' is an excellent supplement to your other works, and will prove a good friend to amateurs in gardening, who greatly need its plain and practical teaching.

Dec. 6, 1876. MARIE HOWLAND, Hammon, N. J."

"Your 'Gardening for Pleasure' I have carefully read, it must become immensely popular—it is thoroughly practical, brief, and comprehensive. Like a good cultivator, you have covered all the ground with the crop intended, showing no weeds or blanks in the field. It is the most complete compendium of gardening I have ever seen.

Jan. 28, 1877. WILLIAM T. HARDING, Florist, Columbus, Ohio."

"'Gardening for Pleasure,' by the author who has already done so much to instruct us of how to make pleasant our country homes, is certain to receive a warm welcome; no subject seems to have been overlooked.

Jan. 8, 1877. HENRY C. BAKER, Wilmington, Del."

"I have read with great interest your very well written book, 'Gardening for Pleasure.' It is full of condensed information, both for the amateur and even the more ex-

perienced in gardening, and I have no doubt it will give pleasure to thousands, as it has done to me.

Dec. 3, 1876. JAMES HENDRICKS, Albany, N. Y."

"I am just in receipt of your 'Gardening for Pleasure,' and if it prove half as interesting to me as your other works, it will be something I cannot well do without.

Nov. 24, 1875. PHILIP HENRY BROWN, Portland, Me."

PRACTICAL FLORICULTURE.

Price, post-paid, \$1.50.

EXTRACTS FROM LETTERS.

"Being a novice, I depended altogether on your book, 'Practical Floriculture,' which I have taken solely as my text book, and my success has surprised me.

Jan. 11, 1878. JOHN C. BONDE, Lexington, Va."

"I have run my greenhouses mainly by the instructions in your book 'Practical Floriculture,' and so far with great success.

April 10, 1877. WILLIAM A. BEERS, Fairfield, Conn."

"I have to thank your 'Practical Floriculture,' which has been the means of enabling me to engage in a business which I trust before long will become as profitable as it is pleasant. I have 2 large greenhouses now stocked with fine plants, entirely propagated and grown according to your directions, which, when disposed of at even moderate prices, I think will pay.

Mar. 15, '76. BENJAMIN C. LODER, Cleveland, O."

"The system of propagating plants, described in your 'Practical Floriculture,' I have followed to the letter, and I doubt if even your own success has been any better than mine.

Jan. 6, 1878. L. C. JOUN, St. Paul, Minn."

"With the instructions received from your works, 'Gardening for Profit,' and 'Practical Floriculture,' I am doing a little both in vegetables and flowers. In both I have been successful, but particularly in flowers.

June 8, 1877. L. C. BARDWELL, Boston, Mass."

"I have nearly all works on gardening, both American and foreign, but I find, whenever I am in a quandary, I look into your little work, 'Practical Floriculture.'

July 25, 1876. J. D. GRAHAM, Denver, Colorado."

WALTHAM WATCHES.

We beg to announce that we have recently entirely remodeled the very popular grades of full-plate movements, known by the marks, "Wm. Ellery," "Appleton, Tracy & Co.," "Waltham Watch Co.," "P. S. Bartlett," and "Broadway," giving to them not only a highly improved appearance, but great additional value. We embody in them such of the best results of our experience and study for twenty years as can be useful in this popular form of watch. We give these new model watches special recommendation to all who look for good performance and solid excellence at moderate cost. The alterations have been made with the view of pleasing practical watch makers, as well as watch wearers.

No watches retailed by the Company. Apply to your local jeweler.

Patents re-issued, and suits for infringement brought and defended. Everything towards procuring patents promptly attended to.

THE "Model Piano."

PRICE \$150 to \$200.

The "MODEL" is a beautiful little Upright or Cottage piano; it is manufactured from the best materials that can be procured; the workmanship is excellent, and its durability is guaranteed; it is small, light, and occupies but little room, is easily transported, and above all the "MODEL" is sold at about one-third the price that is usually paid for any other reliable piano. For the above reasons, it is very suitable for people of moderate means, and those living in small houses; but it is especially adapted for beginners, and on account of its low price, commends itself to every parent, because it possesses all the principal features of the finest piano, and has none of the numerous disadvantages of the reed organ.

For full particulars write for illustrated pamphlet, and state where you saw this notice.

SIMPSON & COMPANY,
PATENTEES AND MANUFACTURERS,

CAPTURING WILD HORSES. — Engraved for the American Agriculturist.

It is generally admitted that the wild horses of our far Western plains descended from European stock. The term *Mustang*, applied to the wild horse in both South and North America, is a corruption of the Spanish *mesteño* (from *mesta*, pasture). In Mexico, and the portions of our territory bordering upon that country, the Mustang is still largely employed, though it is being rapidly replaced by better breeds. Large herds of Mustangs are found on the broad plains of the South-west, and their capture is still followed by both Mexicans and Americans. The usual method of capture is by the lasso, though sometimes, in favorable localities, they are taken by driving into an enclosure. The skill with which the Mexican throws the lasso, is often a subject of comment, but many Americans are quite as expert in this very useful accomplishment of the herdsman. In lassoing a wild horse, or other animal, the horse ridden by the hunter plays a most important part. The saddle is of great strength, and secured by girths correspondingly strong. One end of the lasso (usually 30 or 40 feet long), is made fast to the horn of the saddle, and when the rider makes his cast, which is

done at a full gallop, and the noose falls upon the neck of the wild animal, the horse seems to take as much interest in the capture as the rider himself. When it is necessary to check the captive, the well-trained horse braces himself for the tussle, and renders essential aid. The writer traveled for some months in the region of wild horses, and though "sign" of various kinds was frequent, and our interest was greatly heightened by the wonderful stories told of them, not a drove, not even a single *caballo*, could we see, until at last the party concluded the wild horse to be a myth, and it was the subject of many a joke. Early one morning, a few days out from Corpus Christi, Texas, as we reached a crest of one of the great swells of the prairie, there were wild horses at last, and enough to make up for any former deficiency! As far as the eye could reach, were horses in every direction, in groups and droves—hundreds—no doubt thousands were in view at one time—a sight never to be forgotten! When we first saw them they were quietly grazing, but they soon saw us, and we then found that the wild horse was far from a "myth," and the meeting with them was very unlike a

"joke." Perhaps the white covers of our train of a dozen or more 4 and 6-mule wagons attracted their curiosity, at all events they seemed to wish a nearer inspection, and down they came, in squadrons, regiments, and divisions, circling at full speed, nearer and nearer, their ample manes and tails giving an air of surpassing grace. We did not have long to admire the wonderful beauty of this scene. The mules, from their well-known sympathy with horses, became fairly excited, and soon were unmanageable. It was impossible to keep them in line, and though by firing at the wild horses with rifles and pistols, they took alarm and began to make off, the trouble then was that the mules would make off too! Then followed a "circus," compared to which the "Greatest Show on Earth" is a tame affair. Over 50 frantic mules, and a dozen or more equally frantic Texan teamsters, the mules with braying, trying to go in one direction, and the teamsters, with quite the reverse of praying, urging them to go in another, all emphasized by the *staccato* of the drivers' whips, might not be called a "Great Moral Entertainment," but was a very lively one. In the midst of it all, one

team—to our mess wagon at that—got beyond all control, and went on a full jump for several miles after the horses, before fatigue brought it to terms. The droves of wild horses disappeared as strangely as they came, and when the line of march was resumed, all hands were willing to admit that there were wild horses, but that it was not a good plan to hunt them with a train of mule-teams.

AMERICAN AGRICULTURIST.

NEW YORK, JUNE, 1878.

Hints for Work.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every paper, from the latest experience and observations, by practical men in each department.]

Corn.—The present season is, in the country generally, probably the earliest on record. Much corn was planted earlier than usual, and it is necessary to give extra attention to cultivation. Weeds grow rapidly in such a wet season as this, and should be kept down by frequent working. The forward season may cause growth of stalk at the expense of the ear. As a remedy remove the suckers from the root. A handful of superphosphate of lime applied about the hill now, will help the earing.

Haying.—There will be little hay cut in July this year, unless it is a second crop. Even at the North much has been cut already, and we must hasten to secure the rest before it is over-ripe. The grass and clover being very succulent, will need careful drying. Curing in the cock will greatly improve the quality.

Curing in the Cock, will require two or three days' time. The grass or clover cut in the forenoon may be raked up before evening and thrown into winrows. These may be left until the afternoon of the next day, when they may be thrown into tall cocks, containing about 300 or 400 lbs., and left one day and night to sweat. In this condition the hay ferments and heats, and the excess of moisture is driven off. This process ripens the hay, and improves it very much. After this curing, and a little airing, there is no danger of the hay heating in the mow or stack. To keep the cocks dry,

Hay Cops will be useful. These are made of a square of heavy sheeting (2 yards), with a strong cord on the edges, and having an eyelet hole at each corner. These are placed over the cocks, and tied down at each corner to pegs driven into the hay. They will turn a steady rain of 24 hours' duration, and keep the hay dry. These were described in an illustrated article in the *American Agriculturist* for June, 1876.

Fodder Crops.—A variety of these is better than any single one. Animals love variety, and a change of food is healthful and increases the appetite. Besides a number of well-tried fodder crops, we have some promising new sorts. Of the old ones, oats

and peas, field corn, the large kinds of sweet corn, millet, Hungarian grass, and various root crops, furnish a large choice. Of the

New Fodder Crops, Pearl millet, Golden millet, Southern Cow-peas, and the large mangels, promise to be worth a trial. The two varieties of millet mentioned have yielded immensely, and as a crop for green or dry fodder, and for cleaning the soil, as well as for plowing under for manure, the Southern Cow-pea has been tried successfully. This pea is to be sown now, as soon as may be.

Roots.—Ruta-bagas and white turnips may be sown this month; of the latter, White Norfolk and "Cow's-horn" can be grown and pulled for fall feed in time to be followed by fall grain.

Waste Places may be utilized by plowing and sowing them to some late crop. Every acre and square rod should be made useful in some way, every farm has spots of this kind that could be made profitable, instead of remaining a nursery of weeds.

Cows are now in full flush of milk. As June butter is chosen for packing for winter use, care should be taken to preserve it from all imperfections. This care will be repaid by the better quality. Pure water, good feed, and clean management of the milk and cream, are needed to make the best butter.

Cellars are made damp by inconsiderate methods of ventilation. When a cellar is ventilated in the middle of the day, in an attempt to make it dry, the opposite effect is produced. The hot air is highly charged with moisture; cellar walls and floor are much cooler than the outside atmosphere, and when air is admitted in the day, moisture is deposited as dew on the floor and walls, to the disappointment of the owner. Cellars should therefore be ventilated at night, and kept closely shut up and dark in the day time, especially in hot weather.

Horses.—Fly-time has come, and unless some precautions are taken to rid the horses of their tormentors, they can not do a full complement of work. We find Buchan's carbohc soap, made into soap-suds with hot water, and sponged over the legs and shoulders, and left to dry on the skin, a very good preventive. Cleanliness and darkness in the stables, will contribute greatly to the comfort of the horses at this season.

Sheep.—The ewes and wethers should be tagged and kept free from filth. Many sheep are lost for want of this precaution, by becoming fly-blown. When the maggots have once gained a hold upon a sheep, there is no help for the poor animal; a horrible death—being literally eaten alive by the maggots—is its fate. This can be easily avoided by care.

Lambs.—Early lambs will now need some extra feed. A "lamb-creep," such as was described in the *American Agriculturist*, for April, 1874, will be found useful in supplying the means for feeding the young animals separately from the older ones. To wean lambs easily, turn them into a field, with a few dry ewes, out of sight of their mothers. The mothers will need close watching, lest their udders suffer from retention of the milk. Copious milkers should be relieved of the milk every morning.

Dipping Sheep and Lambs.—At this season, it will be advisable to dip the lambs at least, if not the sheep as well, to rid them of the hateful ticks. A very safe and effective dip is Buchan's Cresylic Sheep Dip, which not only kills the ticks, but cures and prevents scab, and greatly helps to prevent the fly-maggot above referred to.

Poultry.—Young chicks should be pushed ahead as fast as possible. If possible, a good run should be given them. They will do much good in the garden, if the hens can be kept out. A light netting, for separating chicks, dividing runs, or protecting the garden, will be found useful. Mr. H. H. Stoddard, Editor of the "*Poultry World*," Hartford, Conn., has provided means for supplying this want, and informs us that nets of any length and width can be made to order, at very reasonable prices. Those who have so frequently inquired about this kind of nets, will take notice of this.

To use these Nets, plant a few stakes, and run a wire from one end to the other of the row, at the top, and another at the bottom; then stretch the net, and tie here and there to the wires with twine.

The wires may be tied to the stakes with twine, but should be twisted around the end stakes, and these should be driven very firmly, and braced if necessary; but when put up in this way, there is very little strain upon the wires.

Swine.—A run in the orchard, especially if that is sown to clover, will be very helpful for young pigs. There is a mutual relation between orchards, clover, and pigs. The pigs thrive on the clover, and consume all the fallen and wormy fruit; the clover keeps the soil cool, mellow, and moist; and the trees are all the better for the improvement to the soil and the destruction of the insects.

Potatoes.—The potato-beetle has appeared in full force again. The mild open winter has not diminished its numbers. There is but one effective remedy, Paris green. It may be applied in mixture with water—a tablespoonful to a pailful of water—sprinkled on the vines with a whisk, or mixed with flour or plaster—one part to 30 or 50—and dusted on the vines.

Fence Rows.—It is a good practice to move the fences and plow up the fence rows, whenever fields are laid down to grass. We can then have clean fence rows, and get rid of what are nurseries of weeds and collections of trash. Our practice is to take down the fence, lay the rails conveniently on one side, and plow the land; if there are many roots in the ground, gather these to be burned. When the ground is sown, and all is complete, the fence is put up again. It is a very small job to do this once in five or ten years, compared with the convenience of having clean fence rows, which may be readily mown and made to yield a considerable quantity of hay—enough to pay the cost.

Buckwheat is not a very profitable crop, yet there are times and places when and where it may be convenient. Rough places, worn-out sod land, poor stubbles, and hills, may be made to produce buckwheat where little else can be grown. This crop has a good effect upon rough cloddy land, and mellows and softens the soil. Two to three pecks of seed per acre may be sown late this month, or early next. The "Silver Hull" buckwheat is a valuable improved variety.

Notes on Orchard and Garden Work.

The promise of a most successful season in every branch of horticultural production continued until May 13th with us near New York. In the Western States, a cold snap came earlier, and at that date severe frosts in the Eastern States caused much damage, but as we go to press on the 15th, we are unable to state the extent of the losses, which must be wide-spread and important.

Orchard and Nursery.

If tree planting was hurried—and it often is when other work presses—a little attention now may save young trees that might otherwise perish, and it will be well to go through all

Newly-Planted Orchards, and examine their condition before the drouths come. If a tree has been carelessly planted, it may lean to one side; a fault that merely pressing the soil with the foot will remedy. If a tree is a long while in starting, it needs mulching. We have advised that all trees be mulched at planting, but if this is not practicable for the whole orchard, the backward and unpromising specimens should by all means be so treated. See last month's remarks on mulching.

Labels are very convenient, but they often do much harm. Every tree in an orchard, or indeed elsewhere, should be known by its position, and unless a proper record was made at planting time, let it be done at once. Begin and number the rows, from one side, and then opposite the number of the trees in the row, write the name. A permanent record of this kind should be kept, and a copy for convenient reference may be made in a pocket memorandum book. With this, labels are not needed, and generally may be entirely dispensed with.

Labels from the Nurseries are not intended to be permanent. They are usually wired on carefully, the wire twisted tightly so that it may not come off.

They are only intended as a guide to the purchaser until the tree is planted. Look to each tree, and be sure that no firmly fastened label remains; with a very slight growth, the tree may become injuriously strangled. If one prefers to have his trees labeled, let him make sure that the wire allows abundant room to grow. But

A **Safer Label** has no wire. Cut sheet zinc into elongated triangles, about an inch wide at base, and 4 to 6 inches long. Write on these with a black

ZINC LABEL.

lead pencil, and coil the point around a twig, as shown in the engraving. This makes a very permanent label; we have known it to be as distinct as ever for 25 years, and properly put on, they will not strangle. In putting on labels it is well to

Observe a System.—On every tree put them on the same side, N. S., etc., and at the same height as near as may be, otherwise it will be difficult to find them among the foliage.

Grafts set this spring need to be kept watch of; often but one bud will push, and this send out a long vigorous straight shoot, which in heavy winds will be broken or pulled out. Pinch the tops of such shoots to make them branch. Indeed, treat a graft in a tree, as if it were a young tree planted in the ground. If shoots appear on the stock below the graft, break them off while yet young.

Thinning Fruit is Rarely Overdone.—The question of pay can only be decided by trial. If the market is a good one, and labor cheap, it will no doubt pay. If the fruit is marketed in a wagon body, and shoveled up to measure it, it will not pay.

Shoots from Buds put in last summer are to have the same care as those on grafts. They sometimes grow so vigorously, especially on peach trees, that a stake is needed.

Blight and other troubles that befall trees were mentioned last month, and there is nothing to add. This will be an especially busy month

With Insects.—Aside from those mentioned in former months, the borers generally lay their eggs. The perfect insect of the Peach-borer is a small moth, that lays her eggs just at or below the surface of the ground. Heaping up a low mound of earth, or of coal ashes, around the tree, has been found useful as a preventive. When the grub has entered, gum will be found oozing from the wound; the borer does not go much below the bark, and is easily cut out. The Apple-tree borer is a brown and whitish striped beetle with long feelers; this places its eggs near the base of the tree; sawdust from its boring, is a sign of its presence. Cut out, and use a wire if need be, as soon as discovered. The Codling moth worm leaves the fruit, unless that falls, and crawls around in search of a hiding place wherein to make its changes; cloths or hay bands fastened around the trunks catch large numbers; these traps should be examined every 10 days.

Fruit Garden.

Aside from the insects that attack ordinary orchard trees, some peculiar ones are found here. Currants and gooseberries are attacked by the currant worm. See last month for the use of *White Hellebore* for these, and about the attacks of the white grub on strawberries. Large caterpillars of several kinds, and beetles, will be found on grapevines, but rarely so numerous that hand-picking will not keep them in check. A slug-like caterpillar, green, slow, and slimy, often disfigures pear and cherry leaves. Dusting with slaked lime or dry ashes will soon rid the trees of it.

Currants and Gooseberries.—Much pruning in the

fall may be avoided by removing shoots which push now where stems are not needed; they are easily pulled out. Generally the bushes are too full of wood and leaves for the most abundant fruit. In some markets both these fruits bring a better price when picked green—indeed, gooseberries are rarely sold otherwise. By heavy mulching, the fruit of the currant may be kept on the bushes a long while in good condition for table use. For jelly, currants should be gathered as soon as fairly colored.

Raspberries.—The wood, or canes, that fruit this year, will die the next, and the green shoots that are now growing, will bear next year's fruit. If more of these new shoots than are wanted start up, select three or four of the best to each stool, and treat the others like weeds. When the shoots for next year reach 3, or at the most 4 feet, stop them by pinching off the ends. The "Cap" varieties do not sucker, at a distance from the plant, but shoot up from around the base. Keep the new shoots shortened to make a neat bush 2½ or 3 feet high. Thus treated, they will need no stakes. We prefer to cut out the old canes as soon as picking is over.

Blackberries have the same manner of growth as raspberries, and shoots must be treated for next year's fruit. When they reach 5 or 6 feet, nip out the top, which will cause them to branch. Most of them are great wanderers, and all that come up where not wanted should be pulled up or cut off.

Grape Vines.—Sufficient is said about the management of the young vine, especially, on page 222. In moist hot days, examine often for mildew, and on its first appearance dust sulphur freely.

Strawberries.—The treatment of the plants after fruiting will depend upon the plan of cultivation. In any case, the mulch should be removed, the soil between the rows forked over, and the weeds that have come up among the plants pulled up. Where the plants are kept in hills or single rows, the runners are to be cut off. In the alternate plan, the runners are allowed to take root in the spaces between the rows, and the old plants removed, later in the season, after the new ones are well established. New beds may be set from plants struck in pots, as soon as they are well rooted.

Kitchen and Market Garden.

The value of the rake as a weeding implement has often been referred to in these Notes, and at no time is its utility more manifest than now, when the hot weather brings the later weeds on in great profusion. With a long-toothed, wide rake, the surface can be stirred very rapidly, and this will so disturb the germinating weeds that the sun will soon finish them. The frequent use of the rake will save much hoeing. Last month's Notes will be timely in many localities for the present month.

Sowing for Succession must be kept in mind, as the season of many vegetables may be greatly prolonged. Bush Beans, Sweet Corn, etc., by sowing every ten days or two weeks, may be had until frost.

Asparagus should not be exhausted by too long continued cutting. The usual rule is to stop as soon as early peas are ready. Recent inquiries show that it is not generally understood that the crop of next year depends upon the growth of the tops this season, as we have been asked by several if they should not be kept cut off. This would completely destroy the bed. The growth of the foliage is of the greatest importance, as it provides for the buds for next season. Allow the tops to grow until the change of color shows that they have done their work; all weeds that appear should be pulled.

Beans.—If cold storms have injured the first planting of Limas, put in more seed at once. These usually need to be aided in taking to the poles at first. Bush sorts may be put in for succession.

Beets and Carrots.—Sow the main crop if not already in. Weed, and thin when large enough.

Cabbages and Cauliflowers are greatly helped by frequent hoeing. As soon as the early crops are off prepare the ground for celery and other late crops. The seed-beds of late cabbages should be kept free of weeds, and if slugs or insects attack them sprinkle with ashes or lime.

Cucumbers.—The main crop for pickles is usually

sown from the middle of this month to the first of next. For this purpose many prefer drills to hills. Furrows are made 5 to 7 feet apart, well manured, the manure covered with soil, and 12 to 20 seeds sown to the foot to allow an abundance for insects, covering an inch deep. If in hills, make them 6 or 8 feet apart each way, and drop about 20 seeds in each. As soon as the plants appear dust with ashes or air-slaked lime. When the vines begin to run, thin to three in a hill, or a foot apart if in rows.

Egg-Plants should not be put out until the weather is settled warm. They need abundant manuring and constant care to keep them from destruction by the potato-bug.

Melons.—Plant and treat as directed for cucumbers.

Onions require frequent weeding. Our most successful cultivators find a dressing of salt, at the rate of 3 or 4 bushels to the acre, applied when the plants are 4 or 5 inches high, of benefit. For a near market, half-grown onions, in bunches of 12 to 6, according to size, are more profitable than ripe ones.

Parsnips and Salsify are generally left too close in the rows; 5 inches for the one and 4 for the other will give much finer roots than if left nearer. Hoe until the leaves meet across the rows.

Peas.—Sow for succession, though in our hot summers they seldom amount to much.

Rhubarb.—Keep the flower stalks cut off.

Spinach.—The common sort runs up to seed in hot weather; the New Zealand Spinach, a very different plant, flourishes best in hot weather. The seed is uncertain; sow a plenty in warm rich soil, and thin or transplant to 3 feet apart. Beets make an excellent substitute for spinach, pulled before the root is thicker than a quill. The Spinach Beet, and Swiss Chard, are also useful.

Squashes.—The winter sorts should be planted as directed last month.

Sweet Potatoes.—Around New York, the early part of this month is soon enough. See May Notes.

Tomatoes in garden culture should always have some kind of support. Single plants may be neatly trained by a trellis made with three barrel hoops and three stakes. We have given numerous forms of supports in former volumes. The pea trellis given on p. 133, last month, is used, by the gentleman who proposed it, for tomatoes also. Whatever support is used, it should be in place early, as when the plants become large enough to fall over they are very unmanageable.

Sweet Herbs should be transplanted from the seed beds, from time to time, to fill vacant places.

Turnips of the Ruta-baga sorts may be sown at the last of the month or early next. The "Long French" is best for family use, though not large.

Odors and Ends.—Insects must always be attended to. The large green "worm" will make quick work with a tomato vine—hand pick it, for it neither bites nor stings; ditto squash bugs.... Slaked-lime, or ashes, or both, should be freely dusted on all young plants of the squash and turnip families.... See Note last month on "Weeds and Weeder.".... If watering is to be done, do it thoroughly. A mere sprinkling is of little use.... Sashes no longer needed for hot-beds or frames should be carefully put away under cover—Straw mats are to be put away, when dry, in a dry place.

Flower Garden and Lawn.

In most localities planting is done, and there is but little on that subject to add to last month's Notes. Now comes the caring for that which has been planted, and many a novice will find that he has provided a difficult task for himself, and if he does the work himself, will determine to have another year more lawn and fewer beds. A small place well kept is vastly more satisfactory than a large one partially neglected. If one has a suitable locality, he should consider

A **Wild Garden**, which is now becoming popular in Europe, in which hardy plants can grow without any other care than to prevent the strong crowding out the weak. Of course a garden of this kind should not be in a conspicuous place. The surroundings of the house, whether limited or

extensive, should always show careful keeping.

And most important to this end is the care of

The Lawn and Paths.—The frequent use of the lawn-mower, persistent uprooting of perennial weeds, and the clean cutting of the margins, whether they border paths or beds, are all essential to the neatness of the grounds. Weeds must be kept from the paths, as well as the beds and borders, and the roller used when needed.

Bedding, if undertaken in ornamental designs, entails much care in keeping the beds in proper condition. The plants must be kept at a proper height by frequent pinching, and as they become crowded the lines between the kinds must be kept clear and distinct by cutting away those that tend to run together and destroy the effect.

Roses, unless attended to in time, soon present a sorry sight; on the first appearance of the "slug," so-called, the little green caterpillar found on the underside of the leaves, very inconspicuous in itself, but soon sadly noticeable for its work, apply "white hellebore," as directed for currants and gooseberries, under "Fruit Garden." This should be repeated every few days, as long as required. Then the Rose-bugs follow, for which hand-picking is the only remedy, and this is best done when they are quiet, in early morning. Take a tin cup with a little water in it, on which a few drops of kerosene are floating, and knock the bugs off into this. When flowering is over, cut away the clusters.

Fuchsias rarely do well in the open ground unless in a shaded place. They are best on the veranda.

Tuberoses should only be set out when the weather is settled warm, and have a rich spot.

Spring Bulbs, Hyacinths, Tulips, etc., should be kept growing until the leaves begin to fade; then take them up and spread under cover until the leaves are quite dry, when these are to be removed and the bulbs stored in a cool dry place until fall.

Annuals.—Sow for succession, and set out the tender kinds started under glass.

Sundry Matters.—Cut away the clusters from perennials and shrubs as soon as the flowers fade, unless seeds are wanted... Dahlias depend largely upon sticks and strings, are easily broken by storms, and need frequent care.... Stakes will be needed by gladioluses, tuberoses, and other plants. They should be as inconspicuous as possible; if painted stakes are used, let them be brown or some neutral tint rather than green.... If seeds are saved, select from the best always.... Weeds and insects are to be constantly looked for and disposed of.

Greenhouse and Window Plants.

There is but little to add to last month's Notes. As the heat increases, more care in watering will be required by the plants set out, as well as those left in the house. Increase the shading if needed.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our daily record during the year, show at a glance the transactions for the month ending May 13th, 1878, and for the corresponding period last year:

TRANSACTIONS AT THE NEW YORK MARKETS.

Gold has been up to 100%, and down to 100%, closing May 13, at 100 1/2, as against 100 1/4 on April 17th; 102 1/2 on January 12; 103 on December 12; 102 1/2 on November 12; 103 on October 12; 105 1/2 on July 12; 104 1/2 on June 12; 107 1/2 May 12, of last year.... Breadstuffs have been quite freely dealt in, during the month, largely on export and speculative account, but at variable prices, closing, generally, with more firmness. The export movement in No. 2 Chicago (mixed) Oats has been on a liberal scale, mainly for France and Belgium. The opening of the Canals, and the general resumption of inland navigation have served to augment the available supplies of Flour and Grain, especially the latter, and with the very favorable crops and weather reports, have tended to depress prices. In the line of Provisions, business has been less active, and on the basis of reduced figures, in most instances. Hog products have been pressed for sale, with more than usual eagerness. Butter and Cheese have declined materially, and close weak.... A very moderate demand has been noted for Hops, Seed, and Tobacco, within the previous range.... Cotton has been rather more sought after, closing stronger.... Wool has been offered freely, and quoted lower, without stimulating operations, which have been on a moderate scale.... Hay and Straw steady, but not active.... Ocean freights have shown more animation, but at irregular rates, leaving off more steadily.... Grain rates by steam to Liverpool closed May 13th at 8d. (about 16 cents) per bushel; Glasgow, 8 1/2 @ 9d.; London, 7 1/2 @ 8d.; Bristol, 9d.; Hull, 8 1/2 d.; the Continent, 7 @ 9d.; by rail to Liverpool, 7 @ 7 1/2 d.; London, 7 @ 7 1/2 d. 40 bush. Flour to Liverpool, by steam, 2s. 9d. @ 3s. (about 66 cents @ bbl.); by rail at 2s. @ 2s. 1 1/2 d.; London, 2s. @ 2s. 1 1/2 d., and by steam, 2s. 6d. @ 2s. 9d.; Bristol, by steam, 3s. @ 3s. 3d., and by rail, 2s. 4 1/2 d. per bbl. Provisions by steam to Liverpool,

32s. 6d. @ 40s. per ton. Cotton by sail $\frac{1}{4}$ d., and steam $\frac{1}{4}$ d. $\frac{1}{2}$ d. Grain, by sail, for Cork and orders, at 6s. @ 6s. 1 $\frac{1}{2}$ d. per quarter, (8 bushels), and to Continental ports, 5s. 4 $\frac{1}{2}$ d. @ 6s. 6d.; Italian ports, 5s. 6d. @ 6s.; and from Phila. for Cork and orders, 6s. @ 6s. 3d., and from Balt. for Cork and orders, 6s. @ 6s. 3d., and from Phila. for Lisbon, by sail, in bags, 15 @ 15 $\frac{1}{2}$ cts. per bushel.

Beeves.—Business has been marked by a gradual improvement, both in the demand and in the prices; a gain of one cent a pound having been made on the whole, notwithstanding the continued increase in receipts. The quality of the stock offered has also been better than usual; some Colorado steers brought 10c. $\frac{1}{2}$ lb. for 56 lbs $\frac{1}{2}$ cwt., and some Texans 9 $\frac{1}{2}$ c. The Texan drive this summer will be both larger and better than usual, estimates being made of 300,000 head, and the early grass having brought the stock into fine condition. At the close, prices were firm at the advance; a few extra good cattle, 55 lbs. to the cwt., sold for 11 $\frac{1}{2}$ c.; Prime steers, 57 lbs. to the cwt., 10 $\frac{1}{2}$ @11c., and fair natives and good Texans, 56 lbs. to the cwt., brought 9 $\frac{1}{2}$ @10 $\frac{1}{2}$ c. $\frac{1}{2}$ lb. The foreign shipments reached over 1,000 head per week.

The prices for the past four weeks were as follows:

WEEK ENDING	Range.	Large Sales.	Aver.
Apr. 22.....	3 @ 11 c.	8 $\frac{1}{2}$ @ 9 $\frac{1}{2}$ c.	9 c.
Apr. 29.....	8 $\frac{1}{2}$ @ 11 c.	8 $\frac{1}{2}$ @ 10 c.	9 $\frac{1}{2}$ c.
May 6.....	8 $\frac{1}{2}$ @ 11 c.	9 $\frac{1}{2}$ @ 10 c.	9 $\frac{1}{2}$ c.
May 13.....	8 @ 11 $\frac{1}{2}$ c.	9 $\frac{1}{2}$ @ 10 $\frac{1}{2}$ c.	10 c.

Cows have been dull and slow of sale, no good offer being refused. Prices of common cows are \$30 @ \$40, and of good ones \$50 @ \$65 per head; some very good animals were sold at the last price.... **Calves.**—The market, after being weak for the best part of the month, improved along with beef, and became strong and higher. Best N. Y. State veals sold for 6 $\frac{1}{2}$ @7c., and the poorest buttermilk calves brought 4c. $\frac{1}{2}$ lb.... **Sheep and Lambs.**—A marked improvement has occurred in this class of stock generally. Good sheep have been in good demand, unshorn sheep ranged from 6 to 6 $\frac{1}{2}$ c. $\frac{1}{2}$ lb., and clipped brought 4 $\frac{1}{2}$ @6c. $\frac{1}{2}$ lb. Lambs have been lower than ever before known; 6 $\frac{1}{2}$ c. $\frac{1}{2}$ lb. for Ohio; 8@8 $\frac{1}{2}$ c. for Virginia, and 8c. for N. Y. State, having been the rates at the close. As low as \$1.75 to \$1 per head was paid for many.... **Swine.**—With pork down to \$9 per bbl.—lower than for 30 years—hogs have done well at 3 $\frac{1}{2}$ c. $\frac{1}{2}$ lb. for live; dressed have fallen during the month, and closed at 4 $\frac{1}{2}$ c. $\frac{1}{2}$ lb. Pigs brought 4 $\frac{1}{2}$ @5c. $\frac{1}{2}$ lb.

Cocoa and Chocolate.—While coffee and tea allow of various adulterations, these may usually be avoidable by the careful purchaser, but Cocoa, when made up in the form of Chocolate, the cocoa beans being ground to a paste by the aid of heat, can be largely adulterated with materials which can only be detected by a chemical examination. Sugar is desired by many, and this can hardly be regarded as an adulteration, but starch in some of its many forms, plaster, and chalk, are often used to add weight, and red-ochre, umber, and other earthy paints are added to give the proper color. As chocolate and other such preparations are frequently advised for invalids, it becomes especially desirable that it should be pure. The only real safety for the purchaser is in the integrity of the maker of the article. Since our earliest recollections, the name of Baker has been identified with cocoa and chocolate of the best quality. In Europe it is not uncommon for a business to remain in a family for many generations, but such cases are rare with us, and the Bakers are a remarkable instance of the long continuance of a business under the same name, their cocoa and chocolate manufacture having been carried on for within two years of a full century. The present firm, Walter Baker & Co., while adopting modern improvements, maintain the early reputation of the name, by the excellence and purity of their products, and the purchaser feels sure that the name is a guarantee that the article he buys is exactly as represented.

Changes Which Bring Strength.

Mr. Judd's "Silver Wedding."

If ever a man was wedded to any pursuit, Mr. ORANGE JUDD has been to that of Editor and Publisher of the *American Agriculturist*. And it is no stretch of propriety to say that in marking the 25th Anniversary of his connection with this paper, he celebrated his "Silver Wedding." Probably there is no other paper between which and its readers there exists such a peculiar personal relation, as between the *American Agriculturist* and its constituents. This was so noticeable long ago, that it has been very common for us to speak of the "Great Agriculturist Family," and this has of late been manifested to a degree as marked as it is gratifying, in the many hundreds of letters that have come to us with the renewed subscriptions for the present year.

This Pleasant Relation

between Publishers, Editors, and Readers, is largely due to the fact that we have told our friends more about our business successes, our hopes and our future plans, than is customary; we are sure that this has not been without its good effect, in making its readers feel a greater attachment to and confidence in the Journal. Twenty-five years does not seem such a very long time, but when we say that

A Quarter of a Century Ago,

MR. JUDD allied himself with the *American Agriculturist*, and has devoted to it "a quarter of a century" of hard work (which measured by the work of most men, will count a rounded century), it will be admitted that he might properly celebrate his "Silver Wedding" with the paper. We can not now review the many changes that have taken place in these 25 years, at the beginning of which, the circulation was numbered by hundreds, instead of the many tens of thousands it now enjoys—when it was read mainly in a few adjacent States, instead of, as

now, in every land where the English and German languages are read and spoken. At the present moment the future of the *American Agriculturist* is of more consequence than the past, and we with pleasure announce that MR. JUDD celebrates his

Twenty-fifth Anniversary,

by instituting such changes as can not fail to add greatly to the future prosperity of the "Company," and usefulness of the Journal. MR. JUDD's brother,

The Hon. David W. Judd,

who has had a wide and varied experience as a journalist, will now assume an active part in the business of the concern. The business force is still further strengthened by the addition of

Mr. Wm. H. Beckwith,

a gentleman who has had abundant experience in the publication of one of the most successful special, or trades journals of the day, and who will hereafter devote himself to the business of the ORANGE JUDD COMPANY. The occasion was marked not only by strengthening the business force, but the editorial corps is not omitted in the general improvement.

Mr. Edgar H. Libby,

was brought up a farmer, and, after receiving a thorough education in the sciences relating to agriculture, founded the "Scientific Farmer," and until recently was the Managing Editor of that excellent Journal. Mr. Libby will hereafter devote himself to similar duties on the *American Agriculturist*. We make these announcements with all the more pleasure because they are

Additions, rather than Changes.

While "young blood" and fresh energy are added to each department, no efficient member of the force has departed. The business is so large and so varied—and this remark applies to the editorial as well as to the business department—that each one was, formerly, not only overworked, but was obliged to attend to an immense variety of details. These very strong additions to both departments, allow each one, as has never before been practicable, to devote himself to those business or editorial duties for which he is best fitted; and while those who have borne the "brunt of the battle" these many years, do not propose to relax any of their efforts, they hope, by devoting themselves more exclusively to special departments, to make their work more effective. We have given these announcements that our many friends—and no paper ever had more and better—may see that the rounding of a quarter of a century is marked, not by a recital of what has been done in the past, but by immediate arrangements for the more complete accomplishment of the work of

The Next Quarter-Century

of the AMERICAN AGRICULTURIST. It long ago became "an institution," and the most fitting manner in which Mr. Judd could celebrate the 25th anniversary of his alliance with it was, to place it in every respect upon even a firmer basis than ever before, so that its permanence or its usefulness may not depend upon the health or the life of any one person or of several persons engaged in its different departments. Let no one infer that the new arrangements involve the retirement of MR. JUDD. We have figuratively referred to his alliance with the *American Agriculturist* as "a marriage," and this, like all true marriages, was "for life," but they will essentially relieve him from many cares, and really allow him to become more efficient, as he can now put forth his energies in whatever direction they may be most needed. EDITOR.

Last Call.

This is the Last Month for securing the valuable **PREMIUM ARTICLES**, offered in our general list for 1878. All lists must be sent in this month, as the offers will positively cease at 6 o'clock P. M., **June 30**, except as noted below. Our contracts with manufacturers and dealers extend only for six months of 1878, and we can not respond to those who send for premium articles after that date.

But there is *abundant time* THIS MONTH to fill up uncompleted lists, and to start and complete new premium clubs before July 1. Many have done so every year. A very little time and attention will secure free of cost one or more desirable and useful articles. Let all who have not a copy of the list at hand, send us a postal card at once with name and Post Office address upon it, and say on it. "Send Illustrated Premium List."

Over 20,000 persons have already secured some of these valuable articles, and as many more may get them this month. See abbreviated Premium List on page 233.

To Distant Subscribers.—To put all upon equal footing, as thousands of our readers live at distant points, in all parts of the world, we will allow the time of closing the Premium List to be so extended for such distant readers, that every one, every where, shall have 30 days after receiving this paper, in which to gather and forward names for premiums. Those living almost anywhere in the United States or British North American Provinces, will receive this number about June 1st, and thus have a whole month for making up Premium Clubs.

containing a great variety of items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

Publishers' Notices, Terms, etc.—The Annual Subscription Rates of the *American Agriculturist*, postage prepaid by the Publishers, are: One Copy, \$1.50 a year; Two Copies, \$3; Three Copies, \$4.20 (\$1.40 each); Four Copies, \$5.20 (\$1.30 each); Five to Nine Copies, \$1.25 each; Ten to Nineteen Copies, \$1.20 each; Twenty Copies and upwards, \$1.10 each; Single Numbers, 15 cents, post-paid.—The above terms are for the United States and Territories, and British America. To the above add 14 cents extra per year for papers delivered by mail in N. Y. City, and for copies sent outside of the United States and British America, except to Africa, Brazil, British Honduras, the East Indies, and Mexico. For the last named five countries the extra charge is 38 cents per year, to cover extra postage; Single Numbers, 17 cents, post-paid....Remittances, payable to Order of Orange Judd Company, may be sent in form of Checks or Drafts on N. Y. City Banks or Bankers; or P. O. Money Orders; or in Registered Letters, such letters to have the money enclosed in the presence of the Postmaster, and his receipt taken for it, and the postage and registering to be put on in stamps. Money remitted in any one of the above three methods is safe against loss. **Bound Volumes** from Vol. 16 to 36 inclusive, supplied at \$2 each, or \$2.30 if to be sent by mail. Sets of numbers sent to the office will be bound in our regular style for 75 cents (30 cents extra if to be returned by mail). Missing numbers for such volumes supplied at 12 cents each.—**Any Numbers** of the paper issued for 21 years past, sent post paid for 15 cents each; or any full year, sent unbound, for \$1.60....**Clubs** of Subscribers can be increased at any time, at the club rates, 17 new members begin at same date as original club.

Every German Cultivator and Laborer on the Farm, or in the Garden, OUGHT to have the *German American Agriculturist*, and thousands of new subscribers are taking it this year. It contains not only the Engravings and all the essential reading matter of the American edition, but an additional *Special German Department*, edited by the Hon. Frederick Munch, of Missouri, a skillful and successful cultivator and excellent writer. No other German Agricultural or Horticultural Journal in America has been so long issued; no other contains so much useful information and so many engravings. Germans are a reading, thinking people, and know how to make good use of what they read. Many Americans supply it to their German laborers and gardeners; all would find it pay to do so.—*Nothing else can compete with it in cheapness of price for the same amount of material, engravings, etc.*, because the expense of collecting and making these is largely borne by the

American edition, and no separate office or machinery is required beyond German editors and the printers. Its terms are the same as the American edition, singly and in clubs; and clubs can be composed of subscribers for either edition in whole, or in part.—*Please call the attention of your German neighbors to this paper.* It will do much to help new comers to a knowledge of the system and modes of culture used in this country.

A Good Appointment.—The Commissioner of Agriculture has appointed C. V. Riley, who has been for the past 10 years State Entomologist of Missouri, the Entomologist of the Department of Agriculture. Judging from his past, we have reason to expect much useful work from Prof. Riley. The only regret attaching to the announcement, is, that the letter which brings it, also informs us that our old friend Townsend Glover, who occupied the position, has quite broken down in health, and it is feared that his working days are over.

Reliable Business Men, those who have both the *ability* and the *intention* to do what they promise, are the only ones invited to use the business-pages of this journal, and those in charge of that department are under positive instructions to admit no others at any price, and they try to live up to it, and generally do, though once in a while they may make a mistake—to err is human—but *this* seldom occurs. We could make a fortune in a single year, and supply the paper at lower rates, if the advertising pages were thrown open to those who gladly pay high prices, as they can afford to, because they give little for much. But we mean our advertising pages shall be a valuable source of *trustworthy* information to our readers.—When ordering from, or corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of this Journal. They will know what we expect, and what you expect of them as to prompt and fair treatment.

The Winchester Repeating Arms Company, one of the most successful and extensive companies in this country, have leased and fitted up in very fine, attractive style, the ground-floor of the American Agriculturist Building, extending back 114 feet from Broadway, and including the L upon Murray street. Any of our readers visiting the city will be well repaid for a visit to this fine establishment. The Publishers of the *American Agriculturist* occupy nearly the entire first floor above, in four rooms, for General Offices, the Basement for mailing and packing, the fifth floor for editorial rooms, etc., and the sixth floor for printers and engravers. A cordial invitation is always extended to all our friends and subscribers to drop in and see us, whenever visiting the City. The Editors spend much of their time at their various country places, but some of them are usually here a portion of each day. The electrotyping is done at the large establishment of Messrs. Lovejoy & Son, on Vandewater St., and the presswork and folding in the great printing-house of S. W. Green, on Jacob St.

Paris Green.—From inquiry among the manufacturers and dealers, we learn that there are sold in the New York market alone, over 500 tons of this poison annually. One establishment alone, that of F. W. Devoe & Co., sold last year over 150 tons. Nearly all of this is used on the potato crop.

The Frost.—We go to press before full reports come to hand of the effects of the cold spell about May 12th. The area visited by it is unusually wide, and its effects, especially upon tender garden-plants, in most localities disastrous. To what extent the staple grain and fruit crops have suffered, we have yet to learn.

The Tribune's New Printing-Press is one of the most interesting objects to be seen in New York City. In a small compact space stands a machine that draws a wide strip of paper from a continuous roll, prints two copies at a time on both sides, gathers and folds the sheets ready for mailing, and drops them out at the rate of four to five in each second, or 15,000 an hour! All this is done by the machine itself, without the intervention of human hands, except to turn on or shut off steam with a little lever. Any one happening in the city in the early forenoon of any Wednesday should drop in at the Tribune building and see the press in operation.

Advertising Agencies.—Mr. J. H. BATES has taken the large rooms in the New York Times Buildings, formerly occupied by Geo. P. Rowell & Co., and fitted them up finely, and has a well arranged collection of all the newspapers of the entire country. With the advantages here offered, and also at the excellent establishment of S. M. PETTINGILL & Co., so long and favorably known to the press of the country, and which is close at hand, every possible facility can be found by business men who may wish to use the advertising col-

umns of any or all the newspapers and other periodicals issued in America.

The Amer. Pomological Society's Report of the meeting at Baltimore in 1877 greatly exceeds in size, fullness, and usefulness, any of the former excellent volumes. Including the catalogue, it comprises over 200 ample pages, and bears throughout, the evidence of the industry and thoroughness of Col. Wilder, Mr. Barry, Mr. Flagg, the late lamented Secretary, and other faithful workers, and is a volume which is creditable not only to the Society but to the country. The Proceedings are richly worth the membership fee of \$4.00.

Cheap Watches.—Watches are advertised at \$3 and upwards. We have not heard of any one's getting a \$3 watch, though we have seen excuses why they were not sent, and promises to fill the order from the "next lot received." Any one of common sense knows that there must be a limit to the cheapness of a watch that will keep time; the cheapest watch must have a spring and gearing, or "train," must have a face and hands, and the whole must be enclosed in a case.—Of course, if these parts are servicable, no matter where they are made, there must be a point below which the cost can not go. Several weeks ago, Messrs. J. S. Birch & Co. brought us a watch, taken at random from their stock, which they wished us to carry in comparison with our own watch or any other time-keeper. This watch has a case nickel-plated on German silver; beveled crystal, is a stem-winder and a stem-setter; the works, which have a neat look, though not highly polished, are covered with a glass shield, to keep out dirt, and there are, if we mistake not, six holes jewelled. The watch, which is a very presentable one, is called the "Centennial," and has this and a Maltese Cross on the back as a trade mark.—We are thus particular in mentioning the trade mark, as another concern has adopted the name "Centennial" for a very different watch with another device in place of the Maltese Cross. Messrs. Birch & Co., knowing the deception there is in cheap watches, preferred to have theirs tested before offering them. We can only say that the one left with us for trial has thus far proved a most satisfactory time-keeper.

Miles and Acres of Paint.—The largest paint contract ever made, was that of the H. W. Johns' Co., to furnish their Asbestos paint to the Gilbert Elevated R. R., to cover their miles of trestle-work. The surface of wood covered by their paint in the two stores of A. T. Stewart & Co., is estimated at 4½ acres.

The Death of Prof. Henry.—As we are closing these pages the sad intelligence comes to us of the death of Prof. Joseph Henry, Secretary of the Smithsonian Institution. We can only say that not only America, but the world, loses one of its first scientists; there are few remaining whose lives offer so marked an example of pure devotion to science for its own sake. His admirable administration of the Smithsonian greatly contributed to "the diffusion of knowledge among men," while his important investigations and discoveries have made the world his debtor. It was his discoveries in electricity which made the telegraph possible; he established very many important scientific principles, and freely allowed inventors to turn them to profit. He never had time to make money. * * * Since the above was in type, we learn that the Regents of the Smithsonian have elected Prof. Spencer F. Baird, for many years Assistant Secretary, to fill Prof. Henry's position. The best possible thing they could do.

The Umbrella in Agriculture.—It is said that a soldier hired himself to a farmer to dig his early potatoes; after a hearty breakfast, on a hot August morning, the new help seated himself in the shade of the barn, saying to the farmer, "Now, if you want your potatoes dug, bring them along."—"We can not all dig our potatoes in the shade, but there is much exposure to our intense mid-summer heat, that may be, and should be avoided, not only as a matter of comfort, but of health. Sunstrokes are more frequently heard of in cities, as there every easality of the kind goes at once into the papers, while the same percentage of sunstrokes, in a population scattered over a county or two, would scarcely be heard of. We often see a kind-hearted farmer arrange a shade for his horse, while he forgets himself. Of course, most of the active work of the farm must be done under full exposure of the sun, or at least with only the protection afforded by the broad brim of a straw hat. [Mem. do not forget to put a cabbage leaf in that hat.] But in riding, whether upon the mower or reaper, or upon an open wagon along an unshaded road, a full exposure to the noon-day sun can be, and should be avoided. He must be deficient in ingenuity, who can not "conjure up" some screen which shall break the force of the sun, upon the head, at least. These remarks

were suggested by the announcement by Wm. A. Drown & Co., the great Philadelphia manufacturers of umbrellas, that they make a "Wagon Umbrella," especially for farmers, which may be applied to open vehicles of all kinds, including the mower, reaper, sulky cultivator, and other "riding implements." The use of umbrellas by omnibus drivers, truckmen, cartmen, and other drivers, is now very common in cities, and farmers may take the hint from these, and use a wagon umbrella, or other shade, wherever it is practicable.

Waltham Watches.—The Amer. Watch Co. call attention to their new model watch which embodies all the improvements of several years, and which they regard as superior to former styles—however good they proved to be. They are sold by the trade, generally.

To You Gentlemen in Congress.—You have arranged some matters concerning the postal law most beneficially. Other matters are very indefinite, and subject to all sorts of rulings. Here is an example: A farmer in Illinois finds that his seed-corn is destroyed about as fast as he can plant it. The farmer probably labors under the impression that the mail is for the benefit of the people, so as one of the people, he whittles out a neat 6-sided stick, bores a hole lengthwise, puts the insects into the cavity thus made, and closes the opening with a common cork. This is received at his office as 3d class matter. When it reaches us, we are charged 16 cents, because the contents can not be examined. Cases of this kind occur almost daily. The farmer is deprived of the use of the mail if he would send insects, unless letter postage is paid, while the merchant can send samples and haberdashery by the pound. We suppose that postmasters follow what they understand to be the law, but would it not be well to see to the law, so that farmers can receive quite as much benefit from what is called in England the "parcel post," as any other class. As it is now, farmers and naturalists are "left in the cold."

A New Work, Veterinary Obstetrics.—The periods of gestation and parturition are highly important to the owners of valuable domestic animals, as thousands of young animals or dams are lost yearly by mishaps, of which perhaps the mysterious abortion epidemic is by far the most serious. Hitherto stock owners could have no aid, but through (with but few exceptions) a notoriously defective and inefficient veterinary profession. Fortunately, some means of help is now at hand in a new work on Veterinary Obstetrics, by the well known writer, Professor Fleming, of England. This valuable book is profusely illustrated, and complete in details, and we have studied it with great interest. It is necessarily an expensive book, but is worth many times its cost to any owner of but one really valuable breeding animal. A few copies have been received by the Orange Judd Company, which can be supplied at once; others can be procured by ordering them. The price is \$15.00, mailed free.

Cotton Manufacture at the South.—A circular issued by W. H. Oliver, of Newbern, N. C., gives some figures as to the cost of the machinery needed to furnish a cotton factory, and the cost of the supply of cotton in the South. Machinery capable of spinning 1,500 lbs. of lint-cotton daily, will cost about \$13,000, exclusive of a building 50x100 feet, and two stories high, with an engine of 75-horse power. By a new process, known as the Clement attachment to the gin, the seed cotton is prepared directly for the card at a cost of 10½ cents per pound against a cost of 14 cents at ordinary factories. In addition, there is left 3,200 lbs. of cotton-seed, which is valuable for its product of oil and seed-cake. The advantage of a Southern locality for this manufacture is very clearly presented in the circular.

Toe and Heel.—A man wears out his shoes at the heel or at the ball of the foot, while a child's shoes are first "stuffed out" at the toes. Just when this transition takes place, from toe-wear to heel-wear, we are not prepared to say, but it is a question of more practical importance than many over which philosophers endge their brains. We have had a great variety of contrivances to prevent wearing away the heel, and within a few years there have been introduced "tips" for the toes. If a foreigner were to read the sign in Summer St., Boston, of "The American Shoe Tip Company," he might say sarcastically: "In the name of the Prophet—Figs!" "A company, for Shoe Tips, and an American Company at that—here's another Yankee notion."—It is a "Yankee notion,"—and a very good "notion" at that. Children's shoes are sold by millions; if a slight "notion" put to each shoe, will make it—as we have abundant evidence that it does—wear twice as long as the shoe without the "notion," the affair is not so trivial as it might seem, and as this interests every family where there are children in the broad land, the company may properly call itself "American." These tips are merely a metallic plate

formed to fit the toe of the shoe, and turned up in front about a quarter of an inch—just far enough to take the brunt of all the "stopping," and save leather. This great improvement began with copper tips, not desirable for fine goods. These were followed by silver tips, which seemed to be all that could be desired; but the greatest improvement of all is a black tip, finished to so closely resemble leather, that it may be used on the finest quality of shoes, without being conspicuous, or hardly noticeable. It is found that a cap of leather the same as that of which the shoe is made, is of very little service, while the tip places the resistance to wear, just where "it will do the most good." The Shoe Tip Co. claim to be able to prove that the introduction of their tips saves the buyers of shoes \$5,000,000 annually; if the claim be well founded, this, at first sight trivial affair, becomes one of real commercial importance. The tips only are supplied, by the company, to shoemakers in every part of the country.

Directions for Leveling or Terracing Fields.—"J. W. H., Marlow Co., Fla. You will find ample directions for preparing the surfaces of sloping land, to either receive or carry off water without damage, in Stewart's "Irrigation for the Farm, Garden, and Orchard." Although this book relates chiefly to irrigation, yet to make irrigation practicable, the surface must be carefully prepared and drained. These related subjects are also treated in sufficient detail to render the book generally useful.

Death of George Grant, of Kansas.—We regret to announce the death of George Grant, Esq., of Victoria, Kansas, which recently occurred at his residence at that place. Mr. Grant had become widely known as an enterprising resident of Ellis Co., Kansas, where he owned a very large estate, stocked with choice sheep, cattle, and horses. We have frequently noticed the interesting operations of Mr. Grant, and the gratifying success which attended his efforts to introduce high-bred stock into that State. In this he was a pioneer, and his success has led many other persons to follow his example. Until Western Kansas, Nebraska, and Colorado, have become possessed of a large number of fine pure-bred herds. Mr. Grant, a retired English merchant, was an enthusiastic improver of his land and stock, and has done much to benefit his adopted State.

American Berkshire Record.—The American Berkshire Association has done good service to swine breeders in providing a record for pure-bred animals. The value of a pure-bred animal for breeding needs no remark; it is a universally accepted maxim that only a thoroughbred should be used to increase its kind. A record of thoroughbred stock, whatever imperfections may necessarily be attached to it, adds a certain value to recorded animals. To popularize this idea is a good thing, and although some ridicule was at first cast upon a swine record, time has shown good results from it. The Association works not for fame or wealth, but for the interest of breeders, and we desire to call the attention of all breeders of Berkshires to the fact that there is such a Record of which they can avail themselves for a very small fee, and which has become an authentic organ of breeders of these swine.

Cost of a Cotton-Seed Oil Mill.—"W. C., Wilmington, N. C. The cost of the machinery needed for the extraction of oil from cotton-seed, will be about as follows, viz.:

Cost of hydraulic presses.....	\$3,500
Hulling machines.....	850
Pair of rollers for crushing.....	450
Hair mats and bags.....	350
	\$5,150

This machinery will have a capacity for using 10,000 pounds of seed per day, and making 160 gallons of oil and 3,500 pounds of oil-cake. The value of these products will be about \$64 for the oil and \$43 for the cake. Some part of the expenses can be saved by making soap of the residuum of the oil presses and the ashes of the hulls. A cheap building, and a 10-horse power engine, would have to be provided.

Cortland Board of Trade.—A Board of Trade for the sale of cheese has been established at Cortland, Ohio. Sale days are Wednesdays of each week; the hours from 11 to 4. D. D. Marvin, President.

How much Milk for a Pound of Butter?—"T. L. B., Amelia Co., Pa. If milk contains 10 per cent of cream, it will require about 30 lbs. to make a pound of butter. A quart of milk weighs 27/10 lbs., so that about 13½ quarts will be needed.

The Adamant Plow.—"W. L. B., Iliou, N. Y. The two-horse Adamant plow is the one suited for general purposes. This is a very handsome and valuable implement, which has a remarkably easy

draft, a perfectly bright polished surface, harder than steel,—whence the name—and the mould-board is so shaped as to turn a very neat furrow slice as nearly flat as possible. Having plowed our corn ground, both sod and stubble, the present season with one of these plows, we are able to say that it is all that can be desired in a plow. By using movable points, the plow is made much more effective and durable.

Sundry Humbugs.

The selection of the Candle to head the Humbug Column, was suitable in more respects than one. It was originally intended as a warning to those unfortunate who will go blindly for any scheme that promises brilliantly, and who will, even after they have been singed once, try again, like the moths flying towards the candle. While the moths represent those who will, foolishly, be victims, we find, without intending it, that the candle represents a number of popular humbugs. The candle burns brightly for a while, then burns low, then sputters, and at last it is snuffed out altogether. We have had a hand in the work

OF SNUFFING OUT HUMBUGS

for these many years. Among those which have of late been most effectively squelched are the varied forms under which one Elias tries to conceal himself. We find, as in a "Punch and Judy" show, various figures going through with the motions, all with different names, but a look behind the curtain shows but one pair of hands moving the puppets, and the hands are the hands of Elias. This Protean operator does not operate so much as he did. It is but a few weeks since we received

A GREAT MANY LETTERS DAILY,

asking about Russell & Co., Hetherington & Co., Blanck & Co., and others, who offered to dispense freely (for a consideration) gold watches and heaps of jewelry; about various mining schemes, from the most tempting "Silver Mountain Co.," down to the one-horse dodges of Clark & Co., and Keys & Co., with their slips, asking if "this signature is genuine," a full history of all of which is to be found in our former numbers. Apropos of

THESE SIGNATURE SLIPS.

A friend in Pa. writes that the signature which comes back to him must have been cut from his letter to a concern in Greenwich St., N. Y., which pretends to trade in inventions. Our correspondent feels sure that this invention shop is in league with Clark & Co., and all the rest of those who try the signature dodge.

NEW WALL STREET SIDEWALK CIRCULARS,

setting forth that those who send them have peculiar advantages for making a small sum of money into a large one, have appeared of late. We can only say of these circulars as we have said of former ones—The parties who issue them, though they hail from Wall St., are not known to the regular business men of "The Street." do not belong to the "Board of Brokers," and are practically unknown. They mainly come from the cheeky hangers on of the street, who are known to the regular business men as "sidewalk operators" and "gutter snipes." We do not advise our readers to invest money with any one, for Wall St. operations, unless they can afford to lose every cent of it. If they have money which they wish to throw away, there are many respectable brokers who will (for a commission) lose it for them openly and above-board. Pay no heed to these circulars....The good work of the "Massachusetts Society for the Improvement of Agriculture," which allowed us to make last month, such a complete exposure of

JONES & CO., THE "BUTTER COMPOUND" CHAPS,

has been most beneficial in its results, as it has saved the farmers of the country many thousands of dollars, for which these farmers owe abundant thanks to that venerable, but still actively useful Society. Jones appears to be, for the present, perfectly squelched, but he has turned up in so many shapes before (including that of defendant in suits before the U. S. and other Courts, in which he has been heavily fined), that we may look for him again in some other form—like "the old woman who sold earthenware."—"In some tall pitcher or broad pan, *lie in his shop again may stand.*" One of Jones' dodges was, while living and carrying on his business at Ashland, Mass., his letters were mailed and received at South Framingham, three miles, and at Hopkinton, four miles,

distant from that place; yet with all this dodging his mail has been stopped at different times. We have a pretty full history of this young man's career, which may be useful if he starts anew.

HUMBUGS FOR FARMERS AND GARDENERS

are still extant in the offer of most wonderful seeds and plants. If any one wishes to try any of the new and astonishingly prolific kinds of corn, offered from some before unheard of, far-off town, let him go slow; if the corn prove half as valuable as advertised, a small sum invested should produce enough to furnish seed for next year—but let no one risk his crop by sowing *any new thing* to the neglect of old and tested kinds.... Some chaps have been taking orders in Pulaski Co., Ill., for "Thornless Gooseberries," and when the plants were found to have the usual number of thorns, the plea was made that it was the *berry* only that was "thornless." A certain lawyer appears to be actively engaged in

WRITING THREATENING LETTERS

to various parties on behalf of makers of quack medicines, and these parties write to ask our advice. We do not keep a "Law-shop," and our advice can only be given on common-sense principles. If these parties have agreed to do a certain thing, we think that an average jury will decide that they must conform to their agreement, even if the stuff in question is merely a quack-medicine. Unless they are prepared to stand a suit, and are able to show that false representations were made, when they agreed to do certain things, and can show fraud, our advice is, to settle as they best can, and regard the cost of settlement as the price paid for a lesson which teaches them not to

"TOUGH, TASTE, OR HANDLE,"

or have anything to do with any secret medical compound whatever. This is to be said, however, that most of these threatening letters are from "barking dogs that never bite;" they get what they can by threatening a few times with increasing vehemence, and stop short of actual law-suits. If we had been duped into an unintentional agreement about a quack medicine, we would stand a good deal of threatening and a little lawing, if it came.... For many years the *American Agriculturist* fought the war against Humbugs not only unaided, but without the least glimmer of sympathy from any journal whatever, whether "agricultural" or secular—indeed at the present day a journal that claims a leading position in agriculture, and is in some respects entitled to it—persists in the weekly publication of the most evident frauds. If it receives as many complaints of its course as come to us, it must be well paid to allow it to defy the protests of its readers. Just now a word of encouragement comes in

THE CHICAGO EVENING JOURNAL,

which congratulates itself that the laws of Illinois, which make every one who proposes to practise medicine, show a regular diploma, or pass an examination before the Board of Health, have had a most excellent effect; "over 1,200 medical humbugs have been obliged to shut up or leave the State." Elated by this sweep, the "Journal" proposes to go further; it holds that charlatancy and quackery do not attach themselves to medicine only, and proposes a law which shall free the State of

SHYSTER LAWYERS AND CLERICAL PRETENDERS,

and thus purify two other worthy professions.—Go on, brother of the Journal, we are with you in every good work... We have had frequent occasion to say that these columns can not be used for personal ends, and if any one wishes to "get even" with, or expose another, the very place he can not do it in, is the Humbug column of the *American Agriculturist*, which is solely devoted to the public good, and has never, so far as we are aware, been used as a medium for the redressing of private grievances. As these general warnings have not had their full effect, we are obliged to make an example of

A. B. PATTEN, OF GREELEY, COLORADO,

Patten, we have before us your letter to one C. D. P., in Chicago, Ill., in which you complain that some kind of a gimcrack, which you purchased for 25c., is not worth the money. With that we have nothing to do. You say:

"This and others of your advertisements are regular swindles, and I am prepared to make you smart for it. * * * One of our papers offers five dollars for every swindle or humbug exposed by its subscribers. Now, unless in ten days I receive \$10, your name goes into that paper. Orange Judd will hear from me, besides others, and you will be exposed. Don't think I am fooling. I mean business. Send me the money, or you will be exposed."—There, Mr. A. B. Patten, how do you like the look of that in print? You have laid yourself open to a suit for "blackmailing." The courts in the Eastern States are justly severe upon the writers of threatening letters, and would make short work of you by giving you long work on behalf of the State. We hope that the Western courts are equally severe, and that "C. D. P." may test the matter. Patten, you are a high old reformer. You feel that you have been swindled, but can be bought off for \$10. You "mean business," but what very small,

sneaking "business" it is. You would not be worth the prominence we have given you, were it not as

A WARNING TO OTHERS,

against using the name of Mr. Judd, or any other publisher or editor of this paper, or that of the *American Agriculturist* itself in any such manner. We have tried to stop this by giving general caution—hereafter we shall take a more direct method, and name persons and places.

Docks.—"B." The only thing to be done with docks, is to pull them. This is not difficult when the land is moist, and if the roots are large, a bar or lever of some kind may be needed. It is desirable to get the roots out entire, or they will start anew.

Tomatoes and Cancers.—The story has gone the rounds of the papers, that the use of tomatoes tends to cause cancer, and some persons, actually alarmed, write to ask if it is so. Tomatoes are eaten and cancers occur (though very rarely), and we can not prove that the one has no relation to the other, any more than we can not prove that they do not cause baldness, squint-eyes, corns, and crooked little-fingers, but we think they are quite as likely to cause any of these as cancers.

The Cooley System of Setting Cream.—The advantages of a method of setting milk for cream by which the temperature may be kept steady and as low as possible, and access of air to the cream be prevented, are now fully recognized by dairymen. There are several devices for the deep setting of the milk, but only one for the submersion of the deep cans of milk in the ice cold water, which is the most effective. This is known as the "Cooley System," the apparatus for which has been advertised in our pages. We have had their apparatus in use for some months, with very satisfactory success. A report of a meeting of the Chatham, N. Y., Farmers' Club, held January 5th, mentions the exhibition of samples of butter made by a member who had set some milk in open pans, and in the Cooley deep cans. The butter from the deep cans was of very superior quality. A similar report comes from Iowa, where, at the Buchanan County fair a diploma was given for the best creamery butter made by the Cooley process. At this fair, creamery butter is not permitted to compete with dairy butter, else the first premium would have been awarded.

Selling or Using Bones.—"Q. T. G.," Morrow Co., Ohio. Unless there is a bone mill near by, where bones can be ground fine, it is better to sell them at 50 cents per hundred, and buy superphosphate ready made at \$35 per ton. It is a dangerous and troublesome job for persons unused to such work as handling and mixing acids to make superphosphate at home.

Mushrooms.—"J. P.," Ohio. You could hardly raise mushrooms in the open ground during either of the summer months, and it would be difficult to do so anywhere, unless in a cave or cellar, so situated that it would keep at a low and even temperature.

Irish Juniper.—"Postmaster," Potter Co., Pa. The Irish is only a very erect and compact variety of the common Juniper, and it is not possible to say, from a mere bit, what the tree is. It is certainly neither a Hemlock nor a Red Cedar.

White - Crested, White - Polish Fowls, were illustrated and described last month—Mr. Sperry, their owner, writes that he is so overwhelmed with letters that he can not answer them, and wishes us to announce that he has no eggs for sale or to give away.

Grass for Winter Grazing.—"B. W.," Highlands, N. C. The best grass for winter grazing is Kentucky blue grass. This pasture must be kept solely for this use, and not grazed at any other season. It will grow well in decadened timber.

Paris Green for the Potato Beetle.—Abundant experience has shown that there is no known effective remedy against the potato beetle, except Paris green. All other applications have failed, while this is effective, and at once. There are a few important precautions to observe in procuring and using it. The first is, to purchase only a really pure article; an adulterated and cheap one may cause the loss of a crop. F. W. Devoe & Co., Fulton and William Streets, New York, have for some years past given special attention to the manufacturing of pure Paris green, and their packages contain an article that is really pure. Next, an adequate supply should be procured at once, because the price increases with the demand, and at the same time the supply decreases, as the manufacture can not well be carried on in hot weather. The poison should be kept in the most secure manner, and used without waste. Messrs. Devoe & Co. send to applicants a circular with plain and

practical directions for using the poison.—And we will add that with proper care, Paris green is a safe article to use; that it is the great remedy against this Potato pest—that a tablespoonful of it in a watering-pot full of water, and having a sprinkling nozzle, can be readily and easily carried and applied to the potato vines affected, with a certainty of killing the beetles. The Paris green does not dissolve; hence the need of keeping it constantly stirred or shaken up in the water, as it is applied. We have tried this with gratifying results. There are various useful contrivances for applying the green as dry powder mixed with flour or other divisor.

What is a Hone.—"D. C. C.," Roselle, N. J. A road scraper or leveler would hardly be recognized under the name of "hone." The use of the word "hone" for this implement on Long Island, must be local only. It is always best to call a thing by its commonly known name, as this saves much explanation. Everybody would know what a "road-leveler" is.

Tree Roses.—"F. A. B.," Mercer Co., Pa. These can not be classed as humbugs, although the representations made concerning them may be fraudulent. There is no special variety known as the Tree Rose, as almost any rose may be made into a "tree" by budding it upon the stem of a Dog-rose, at the height of three to five feet. If "thousands of dollars" have been expended for these roses in your county, it is quite time that the people knew that they are quite unsuited to our climate. The hot sun scorches the tall naked stock, and the top is killed by the winter; they seldom last more than two years, while the majority are finished the first winter.

Kidney Worm in Hogs.—"F. H. N.," Rowsburg, Ohio. When a pig is paralyzed in the hind-quarters, it is not always the effect of worms in the kidneys or in the loins; worms are very rarely found in the kidneys, but more frequently infest the muscles and fatty tissues of the loins. In the majority of cases, however, the paralysis is caused by a disease of the covering membrane of the spinal marrow, and consequent effusion which interferes with the operation of the nerves of the locomotive and digestive apparatus. The remedy is a counter irritant, such as turpentine or mustard applied to the loins, and a diuretic which relieves the pressure of the effused serum. One ounce of turpentine may be given in two ounces of linseed oil every second day, or one dram of saltpetre may be given every day. The turpentine will be useful in case worms should be the cause of the trouble.

Feeding Cows for Milk.—"N. P. M.," Columbus, Ohio, writes:—What is the most profitable way to feed cows; to give the meal dry, wet with cold water, or wet with hot water; with labor at \$20 per month, corn worth 40 cts., oats 25 cts., and 7 cts. a bushel for grinding? My present practice is to haul out the manure as fast as made, returning with a load of fodder. The manure is spread as hauled. The meal I feed dry. I have just commenced a milk dairy, and desire to get the largest amount of good milk at least cost. My practice is to feed one-half basket of fodder at 5.45 A. M. to each cow; milk at 6, at 7 turn out to freshly-pumped well water. While cows are out the stable and mangers are thoroughly cleaned; then 6 quarts of meal given to each cow, and one basket of corn fodder. The cows are then allowed to come to their stanchions, and at 12 M. have one to one and a half basket of fodder. At 4 P. M. the cows are again turned out to fresh water, while the stables and mangers are cleaned; then feed 6 quarts of meal and $\frac{1}{2}$ -basket of fodder, and the cows returned to the stable. At 5.45 P. M. feed one basket of fodder. At 6, milk, and close up the stable for the night.—[We can not see that the above practice can be improved upon.]

Swine, Pigs, and Pork.—It is not surprising that there should be a large demand for works upon swine, when we consider that these animals—taking the country through, and at a low valuation—are estimated as worth about \$70,000,000. Swine are so rapidly multiplied, and so easily raised, that in some parts of the country—even where they are most valuable as a farm product—they have been sadly neglected. The idea that "one hog is as good as another," has prevented proper attention to the breeds, and the treatment indicated by "root hog or die," however it may have resulted as to *rooting*, has led to *dying* by wholesale. The results of this management, or no management, have had their proper effect. When a farmer who has depended upon his pork for a large share of the ready money that comes to him in the course of the year, finds his swine suddenly swept off by hundreds, and he stands helpless and without remedy, it is a low heavy enough to make him stop and inquire "why is this?" The best answer that we can make to all who have suffered similar losses, or who fear such, is, get Coburn's "Swine Husbandry," and study it carefully. This work, while full in other matters, gives special attention to the diseases of swine,

and shows very plainly that the much and justly dreaded "Hog-Cholera," is to be regarded as an *avoidable disease*. The appearance of this fatality among swine, is, in many cases, an indication that years of neglect have produced their legitimate results, and though when it once appears, it may be communicable, swine in a proper sanitary condition are not liable to its spontaneous outbreaks, and are much less subject to take it from others, than those which have been systematically neglected. This work is by a large breeder of swine in Kansas, and gives in full the Western methods with these animals. A work not the less valuable of its kind, is "Harris on the Pig," which takes up the subject in a different manner, and is full upon the origin of the different breeds of swine and their characteristics. It gives special attention to the value and management of thoroughbred animals, and while its author as unmistakably gives preference to the Essex, as Mr. Coburn does to the Berkshire, other breeds have their merits fairly set forth. This work gives much in the detail of pig management that the other does not touch, and the two works together may be regarded as a *library*, embodying the present knowledge on "Swine, Pigs, and Pork," as set forth by two eminently successful breeders in widely separated localities. Both works are published by the Orange Judd Company, and are sent post-paid, Coburn's for \$1.75, Harris' for \$1.50.

The Potato-Beetle—Paris Green—An Englishman on.

—The Colorado Potato-beetle or Potato-bug, being a genuine native American, of course the proper place—as such things go—to find the latest intelligence concerning it, is in an English Journal. That most excellent monthly, "Hardwicke's Science Gossip," had a few months ago a letter from one W. V. Andrews, "Corresponding Secretary of Long Island Entomologists Society, U. S. A.," in which are statements of such a remarkable character that the author hardly needs to state "I am an Englishman;" for no American familiar with the subject could have made them. This "Secretary" advises his "countrymen," in case the Potato-beetle should appear there, to "use no Paris green." The reasons for this advice show that he knows nothing about Paris green, and that whatever entomological knowledge he may have of *Doryphora*, he has had little practical experience with "tater-bugs in the field. Hear him: "For larger lots [of the beetle] the ordinary butterfly hag-net, swept gently along the potato tops, will capture more beetles in an hour than Paris green will kill in a week!" Will the "Secretary," when he goes out hunting with his "ordinary butterfly drag-net," state how many *larvæ* he finds in his ordinary entomologists "drag-net?" Those who have any practical knowledge of the beetle, as an agricultural pest, will be prepared for the absurdity which follows. This Secretary says: "Mr. Rye tells you that Paris green is a favorite remedy here, but he does not understand the American way of doing things. Some State entomologist, or other, probably had a friend in the oil and color business, and gave a friendly puff to Paris green. Then the oil-and-colorman advertises in some agricultural papers that he has the 'never failing exterminator of potato-bugs, Paris green,' and the editor of that journal at once *strongly* recommends it. You do not do things in that way in honest old England, but we do here."—This Andrews is both impudent and ignorant. As to "some State Entomologist or other," we can now recall but two "State Entomologists," both of whom are practical men, who are known for their services to agriculture, and could no more advise the use of Paris green, or any other article, from interested motives, than they could malign another by the indirect method shown in the quotation. The dig at "the editor" of "some agricultural papers," (though "an Englishman," this Secretary's English is none of the best), is something that is so bewilderingly stunning that we do not know what the effect may be when it becomes known that there is such a man as Andrews, and he has written all that. As one of the "editors" we say—if it is the last scratch we are to write, we *will* say it—"Now, Andrews, don't!—No, they do not" do things in that way in honest old England."—Here, if one finds a useful remedy, he tells what it is, and allows every one to use it, knowing just what he is handling; and if dangerous, he knows how to guard against its injurious effects. In that 'onest h'old H'England they have not—and more's the pity—"the American way of doing things." In that beloved country—Oh, "W. V. A.," why did you leave it?—if one finds anything that will kill a plant louse even, does he publish the remedy?—Not much! He first writes to the papers, and tells the public that he has discovered "Suthink." After a while the stuff appears in papers or bottles, labelled "Gishnert's Compound," "Fowler's Insecticide," "Abysinnian Compound," or some such thing, and we are sorry to say that respectable papers not only allow such arrant quackery to be advertised in their columns, but actually recommend the use of the stuffs, of the composition of which they probably know nothing. This

Secretary so dislikes "the American mode of doing things,"—things are done so much better in "honest old England"—that we advise him to take his "ordinary butterfly bag-net" and go home. He will never be missed from the scientific circles of the country he has maligned. For the benefit of those Englishmen who may be in search of information concerning the Potato-beetle (we do not suppose it possible to teach the "Secretary" anything), we will say that the *best, fullest, and most reliable* account of the insect, its natural foes, and its proper treatment, is to be found in a work called "Potato Pests," published by the Orange Judd Company, and to be had of Trubner, London, and no doubt of other booksellers. This work is by Prof. C. V. Riley, who is one of our first scientific entomologists, and easily the *first* in the practical application of entomology to agriculture and horticulture. It is true that he has the misfortune to be "some State Entomologist," still he is not only "an Englishman" but at the same time a man of science, and a gentleman, and he is not, to our knowledge, the "Secretary" of any thing.

Poultry Literature.—None of the "minor economies" of the farm are more important than the poultry-yard. It not only supplies eggs and fowls for the table, but is often the chief reliance of the housewife for pocket-money. But there is no point on the farm in which the difference between good and bad management is more strikingly manifest, and the difference between success and failure is an important one. After a careful examination of the various works on poultry management, we found none so clear and concise, or of which the teachings were more strongly marked by common sense, than Wright's "Practical Poultry Keeper," and what is very unusual in an English work, it appeared to be quite as well adapted to our conditions as those of English poultry keepers. Arrangements were made by the Orange Judd Company for its publication in this country, and it remains the best general standard work on the subject. [Sent by mail for \$2.] A smaller, more compact, and very useful work is Saunderson's "Domestic Poultry," by a gentleman who has been a very successful exhibitor of poultry. [Sent by mail in paper for 40c., and bound in cloth for 75c.] An important series of articles written for the *American Agriculturist*, by H. H. Stoddard, now editor of the "Poultry World," Hartford, Conn., has been collected and published under the title of "The Egg Farm." While the teachings of this are directed toward the greatest production of eggs, it contains much that is useful to those who raise poultry for their flesh. Indeed it is a real store-house of practical hints and suggestions. [Sent by mail, in paper covers, 50c., in cloth, 75c.] In his "Poultry Yard and Market," Mr. Corbett gives his experience with his style of incubation, and artificial mother, and various other matters of interest to the poultry-raiser. [By mail, in paper, for 50c.; in cloth, 75c.] These works are all by practical men, and together cover about every aspect of poultry-management. Those who wish highly ornamental works, in which the breeds are illustrated by fine colored plates, can for \$9 procure Tegetmeier's Poultry book, a standard work by the most eminent English authority on the subject.

An Index to North American

Plants is a more popular title than "Bibliographical Index to North American Botany," and we choose here a popular title to commend to Nurserymen, Florists, and others, a work which, though compiled especially in the interests of botanists, can not fail to be of the greatest utility to all who have to do with plants and who care to refer to original sources of information. Every one interested in native plants, whether herbs, shrubs, or trees, is aware how widely scattered is the information relating to them. Botanists will understand its value from its proper title, which we have given. We can best give an idea of its utility to nurserymen and others who wish to know about plants, by a single illustration. We turn at random to our common Thilip-tree (incorrectly "Poplar" in some States), and find 41 references to works in which it is described or noted; and it is moreover indicated, by the use of full-faced type, that in 18 of these places there are figures of the tree, or some portion of it. The references are not confined to botanical works alone, but horticultural books and periodicals are also quoted. What is done for this one tree, is done for all other trees and plants, and it will be seen from this example, that this index is a key to all the sources of information concerning every North American plant. The work is by that acute and pains-taking botanist, Mr. Sereno Watson, of the Herbarium of Harvard University, who has done an eminently good thing for not only botanists, but horticulturists generally. Of course such a work, so brain-wearing and time-consuming, can never "pay," and we doubt if it could ever have found a publisher, had not that most useful Institution, the Smithsonian, assumed the publication, as one method of "diffusing knowledge among men." The first vol., extending through the poly-

petalous families, is now out. A limited number of copies, at \$2.00 in paper, and \$2.25 in cloth, by mail, post-paid, may be had by addressing "Curator of Harvard Herbarium," Cambridge, Mass.

The Plants of North America, or of

any other country, taken together, are called its "*Flora*," just as the animals constitute its "*Fauna*." When we speak of the "Flora of North America" we may refer either to the plants themselves, or with equal propriety, to a work describing these plants. "North America," so far as its "Flora" is concerned, starts from our southernmost boundary, and extends northward as far as vegetation of any kind exists. We frequently see mention of the varied agricultural capabilities of our country, affording sugar-cane, and the banana, and extending through various zones, until we reach a point where the only crop is ice. Quite as wonderful in its extent and variety is the native vegetation. Let one start from Southern Florida with its tropical and subtropical plants upon one side, or from Western Texas, Arizona, and Southern California, with their almost Mexican vegetation, on the other, and pass northward along the Atlantic coast, or along the Pacific coast, or starting part-way (though not mid-way), between, along the great mountain ranges which form the "back-bone" of the Continent, and continuing upon either line until the Arctic regions are reached, the number and variety of native plants that such a traveler would meet with, is immense. Yet one must enumerate and describe all these plants, growing in such a variety of climate and locality, if he would record the plants of our country—or in other words, write a "Flora of North America." Several Europeans, in the early part of the century, undertook this task, but "North America" as here defined, was unknown to them. About 40 years ago, the lamented Doct. Torrey, together with his then young associate, Doct. Asa Gray, made a noble beginning at the "Flora of North America," and carried it well along, but just then North America increased too rapidly, and among other reasons, the want of settled boundaries made it necessary for them to suspend the work. Our boundaries being now well established, the newly acquired territory having been well explored, Doct. Gray has now undertaken the task of recording the plants of this vast country, and we have already received the first instalment of "The Flora of North America." Botanists will learn of this work and its peculiar features from other sources; but there is a large class of persons, not scientific botanists, who are interested in knowing that a work, in which every native plant of the whole country is recorded and described is in course of preparation and publication. The work will be in two volumes of about 1,200 pages (large 8vo.) each. For reasons which botanists will appreciate, the new work begins where the earlier work of Torrey and Gray, just alluded to, left off. The present part, one-third of the second volume, includes the Monopetalous Exogens (*Gamopetalæ*) beyond *Compositæ*. The unbotanical reader will better understand its scope when we say that this part includes, among other large families, the Heath Family, with so many highly ornamental plants; the Milk-weeds and the Gentians; the Phlox and allied families, rich in garden species; the Borage, the Morning Glory, the Solanum, the Fig-wort, and the Mint Families. For the botanical character of the work, it is sufficient to say that it is by Doct. Gray, and indeed we may say the same of its mechanical aspect also, for being printed under the critical eye of the author, it presents that judicious arrangement, and convenient grouping that will be best appreciated by those who most frequently consult the work. New York: Ivison, Blakeman, Taylor & Co., p. p. 402, price \$6.00. Supplied from this office.

Bee Notes for June.

BY L. C. ROOT, MOHAWK, N. Y.

This, in most sections, is the general swarming month. Those who practise natural swarming, should have hives ready, and kept in a shady place. After the bees are hived, protect the hive from the rays of the sun, with a roof, or other cover. Swarms are often lost by going to the woods, if these directions are not followed. I much prefer artificial increase. Where but few swarms are kept in hives with movable frames, an occasional examination may be made, and if queen cells have been made, it will indicate the proper time to divide the bees, which may be done as follows: Remove the hive from which the swarm is to be taken to a new position, several feet distant, and put a new hive in its place. Take one comb, containing brood, the old queen, and all the bees that will adhere to it, from the old hive, and place it in the center of the new one. All queen cells should be removed from this comb, or one selected that has none

upon it. Fill the space at each side of this with empty frames, and place an empty frame in the old hive at the outside. After the queen cells in the old hive are all sealed over, cut off all, except one of the largest and best looking, from which the colony may be supplied with a queen. Or, what is greatly preferable, a laying queen may be given it the day after dividing.

Weight of Bees.

No. 1 has been united with another, and, therefore, cannot be reported. No. 2 consumed, during April, $4\frac{1}{2}$ lbs. of honey, No. 3 and 4, $3\frac{1}{2}$ lbs. of honey each.

Cow Milkers.

Many inquiries have been made in regard to "Milking Machines"; replies to these by mail have been impracticable on account of their number. We therefore take this opportunity of stating what we know of this machine. The idea of milking a cow by means of a mechanical device is attractive on the face of it, because this operation is one of the most irksome of all farm labors. There has been a prejudice against the use of any other methods of milking than the old fashioned one, and we confess to have felt to some extent the influence of this prejudice, and have been very cautious in referring to the Milking Machine. For exceptional use in the cases of sore or chapped teats, hard milking cows, gargeted or caked udder, and other similar difficulties, there has never been a question as to the necessity for using a milker; some such means is indispensable. But for general use to save time and labor, we have not previously been able to say that the machine was advisable. After a personal trial we must admit that we have been forced to modify our previous opinions. We give an illustration of the machine and its manner of use. The tubes, of pure silver, are inserted carefully in the teat, the milk having been first started, to allow the opening to be found. The pure India rubber tubes then conduct the milk, which flows freely into the pail. That is all there is of it. Care must be taken to use only such machines as are of pure material, and after the milking to put the tubes into some clean, cold water, and well free them from milk. In using the machine, we find it operates as follows: It draws the milk so entirely

THE COW MILKER.

away that none can be procured by stripping; it acts apparently with much ease and comfort to the cow, our animals evidently showing much surprise and pleasure at the freedom from the usual manipulation of the teats, and turning the head and viewing the novel process seemingly with great interest; the milk pours with great rapidity, a large pail, holding 14 quarts, being filled in 7 minutes; the process is perfectly clean, and the milk gathers no impurities, as in the usual handling of the teats and udder, in which numerous scales of skin, hairs, and "cowy" flavored matters unavoidably fall into the milk. The relief from the muscular exertion of the wrists and arms, is very grateful to the milker. So far we are certain. Of the future effect upon the cow we are not prepared to say, because this is a matter which can only be learned by the continued use of the milker; but there is evidence that the machine has been used in a noted Scotch dairy for 8 years, and this may go for something. As it is, we shall continue to use it, and take whatever risk there may be. As the tube is very small, and is retained in the teat only 3 or 4 minutes, and the teat is to be stripped down always after finishing milking, we apprehend no evil results. For the introduction of the milker into this country, we are indebted to Mr. Wm. Crozier, of Northport, Long Island, who has introduced several useful implements to American farmers

The Hay Crop and How to Gather It.

The present season has thus far (the middle of

Fig. 1. OPEN. NOYES' GRAPPLE FORK. 2. CLOSED.

May) been very favorable for a large hay crop, and the labor of gathering it will be greater than usual. There is likely to be an extra large demand for haying machines and "tools." We have already spoken of mowers, conspicuous among which stand the Champion Haymaker, and the New Model Buckeye. After the mower comes the tedder, a machine which, in thick clover, will be found of great use to spread and turn the cut herbage, and prepare it for the rake. Of the tedders, we have used one made by the Ames Plow Co., while another

Fig. 3.—FIELD PITCHING APPARATUS.

style, made by the Higganum Manufacturing Co., has impressed us favorably. The steel-tooth horse-rake is doubtless one of the most effective implements in the hay field. Of the large number in the market, that made by Wheeler & Melick Co., and another, made by J. R. Whittemore, are excellent implements. When the hay is gathered, Foust's Hay-Loader will load a wagon in ten minutes or less,

Fig. 4.—AMERICAN HAY ELEVATOR.

and where the crop is large, will be indispensable, if economy of time and cost is the first consideration. This loader was illustrated in the *American Agriculturist* of Nov., 1876. After the hay is loaded, the Horse Hay-Forks and Pitching Apparatus, by which it is put away in the barn or stack, are perhaps the most important of any of the labor-saving haying machinery; because after a crop is well made, it may be seriously damaged by heavy rains before it can be secured in the barn or the stack by the usual slow methods. Some of these hay-forks have already been described in the *American Agriculturist*, others are briefly referred to as follows. The "Noyes Grapple Fork," shown open at figure 1, and closed at figure 2, is an excellent implement, and can be used for hoisting straw, corn-stalks, or sheaves of grain. This is made by the "U. S. Wind-engine and Pump Co.," Illinois. The same Company also make the "Field Pitching Apparatus" (fig. 3), used

Fig. 5.—DOUBLE HARPOON FORK.

for stacking hay. The "American Hay-Elevator," shown in figure 4, is made by J. R. Fitzhugh, of Pennsylvania. This can be fitted to any building, and has the merits of being simple and easily worked. The "Double Harpoon Fork," made by the "Pennock Manufacturing Co.," Penn., (fig. 5), is a fork of great capacity and strength, and may be used in short straw, hay, or hound grain. Another pitching apparatus, of which we have no illustration at hand, is Chapman's. Of the comparative merits of all these, it is difficult for one who has not tested them all to speak. Before deciding it will be well to procure circulars of the various makers, and examine into the merits and testimonials of each. The P. O. address of the makers can be found in the advertising columns.

Science Applied to Farming.—XLII.

The Use of Brains in Farming—A Lesson in Chemistry.

On the blanks for recording results of experiments with the fertilizers supplied for experiments this season, is the motto: "One of the chief wants of our agriculture is closer study and observation by farmers." In an account of last season's experiments, presented at a meeting of the Conn. State Board of Agriculture, occurs the following:

"These reports are presented for just what they are, not developments of any new scientific truth at all, but efforts by practical men to apply established principles of science to the aid of their farming. And if I were to tell the truth, it would be that in my opinion, though such experiments, properly conducted, will be of the greatest value for the information they bring, yet, over and above this they have a still higher usefulness in the stimulus they give to closer study, more accurate observation and more rational application of the principles of science. The apparent object in introducing them was to work upon farmer's soils. Under this lay in my own thought, a deeper purpose, to work upon their owner's minds. And in this regard, at least, the outcome has been most gratifying."

We shall be aided in our efforts in this direction by

A Short Lesson in Chemistry.

Vegetable and animal substances, and manures and soils as well, contain three kinds of material—WATER, ORGANIC MATTER, and MINERAL MATTER, or ASH. If you keep a visp of hay or a hone for a time in a hot oven, the water will be driven out. If you put the dried material in the fire, the organic substance will be burned away, and escape as gas or smoke, while the mineral matter will be left as ashes. The ash was all gathered by the plant from the soil. Part of the organic matter was supplied by the soil also, but the most of it came from the air, to which it returns when it is consumed. The ORGANIC MATTER consists chiefly of the four chemical elements, CARBON, OXYGEN, HYDROGEN, and NITROGEN. We are familiar with carbon in charcoal and lamp-black, which are nearly pure, and in diamond which is quite pure carbon. Carbon united to oxygen forms carbonic acid. Hydrogen and oxygen, which in their pure state are gases, unite to form water. When we inhale air in breathing, its oxygen is absorbed into the blood through the lungs, and unites with carbon and hydrogen of our bodies and our food, and we exhale carbonic acid and water. When wood burns in the stove, or vegetables decay in the air, carbonic acid and water are likewise produced. We need not trouble ourselves about carbon, oxygen, and hydrogen, in fertilizers, because they are supplied to the plant in abundance by the atmosphere and the soil, through the leaves and through the roots. But the

Nitrogen

is an important ingredient of fertilizers. It is, in its pure state, a gas, and makes up about four-fifths of the air, the other fifth being oxygen. Nitrogen combined with hydrogen forms AMMONIA. The odor of "spirits of hartshorn," and of "smelling salts," is due to the ammonia. Nitrogen, combined with oxygen, is known as NITRIC ACID. In these and other combinations it occurs in minute quantities in the atmosphere, and in considerable quantities in soils and manures. Plants are unable to make use of the pure nitrogen of the air, though they absorb a very little combined nitrogen, in the

form of ammonia, nitric acid, etc., from the atmosphere. By far the largest part of the nitrogen of plants is absorbed from the soil through the roots. Nitrogen is available to plants only in certain combinations; is slow to form these compounds, and easily leaves them. It readily escapes from the manures and soils into the air, and is leached away by water. It is one of the most commonly deficient, and hence the most costly ingredients of the food of plants. Farmers are continually paying from 20 to 40 cents per pound for nitrogen in fertilizers, and their crops often fail for want of it.

NITRATES are compounds of nitric acid with other materials called bases. Thus nitric acid united with the base soda, forms *Nitrate of Soda*, which is one of the most valuable of our fertilizers.

The Mineral Matter or Ash

consists of several ingredients, of which the names are Potash, Soda, Lime, Magnesia, Iron, Silica, Sulphuric Acid, Phosphoric Acid, and Chlorine.

POTASH.—The basis of this is a very soft, light, silver-colored metal, called *Potassium*. Potassium unites with oxygen to form a compound which is known in chemistry as potassiumoxide or oxide of potassium. It is also called *potassa*, or more familiarly, *potash*. When wood ashes are leached the potash is dissolved out, and it is the active ingredient of the lye.

SODA, or sodium oxide, is a compound of oxygen with the metal *Sodium*. What is commonly called soda, is *carbonate of soda*, a compound of soda with carbonic acid. Common salt contains sodium also, but here combined with chlorine instead of oxygen. *Chlorine*, by itself, is a yellowish green gas. As it unites with sodium to make *chloride of sodium*, or common salt, so, when united with potassium, it forms *chloride of potassium*. Potassium chloride is the chief ingredient of "muriate of potash," one of the most important of the German Potash Salts.

LIME (calcium oxide), is the basis of limestones, marble, oyster shells, and the like. In these it is combined with carbonic acid in the form of carbonate of lime. By heating limestone the carbonic acid is driven off, and lime is left in its common caustic unslaked form.

MAGNESIA is the oxide of the metal magnesium. The "calcined magnesia" of the apothecaries is impure magnesia, with the carbonic acid expelled.

IRON is the same element, whether found in plants, manures, or soils, in which it invariably occurs in very small proportions as an oxide, or in the various ores from which it is manufactured on a large scale.

SILICA.—Quartz, or "rock crystal," is pure silica. Flint is nearly pure silica. Silica combined with various other elements, makes up the larger part of the rocks and minerals of the globe. Sharp sand consists chiefly of silica.

SULPHURIC ACID.—SULPHUR is familiar to every one in the forms of brimstone and flowers of sulphur. Sulphur united with oxygen, forms sulphuric oxide, or, as it is more frequently called, sulphuric acid. The ordinary sulphuric acid of commerce, called "Oil of Vitriol," and used in making superphosphates, consists of sulphuric oxide with a small proportion of water.

SULPHATES.—If sulphuric acid and lime are mixed together, they will unite and form a chemical compound, *Sulphate of Lime*. Gypsum or plaster is a more or less impure sulphate of lime. Sulphuric acid and magnesia make *Sulphate of Magnesia*, which we know as Epsom Salts; it occurs in some of the German Potash Salts. So *Sulphate of Soda* consists of sulphuric acid and soda. *Sulphate of Potash*, the basis of the best potash salts, used as fertilizers, consists of sulphuric acid united to potassa. *Sulphate of Ammonia*, which is a valuable fertilizer, consists of ammonia and sulphuric acid.

PHOSPHORIC ACID.—Phosphorus is the material which is used for the tips of friction matches, and

causes them to shine when rubbed in the dark. It burns very easily, and in so doing unites with the oxygen of the air, and forms phosphoric oxide, or phosphoric acid.

PHOSPHATES.—Just as sulphuric acid combines with lime, potash, and other bases to make sulphates, so Phosphoric Acid unites with the same basis to form phosphates. Phosphate of lime is the most important of the phosphates. It is the basis of bone. When bones are burned, the water and organic (animal) matter are driven off, and we have left the bone-ash, which is nearly pure phosphate of lime. The South Carolina, Navassa, Canada, and other fossil and mineral phosphates, which are used for fertilizers, contain more or less earthy matters mixed with the phosphate of lime.

Whence Plants obtain their Supplies of Food.

Plants get part of their food from the air, through their leaves and other green parts, the rest from the soil through their roots. This is proven by a vast amount of laborious and accurate experimenting, carried on for the most part in the European Experiment Stations, for the purpose of discovering the laws of plant nutrition and growth.

WATER.—Plants have the power of absorbing water through their leaves, but the bulk of their supply comes, and must come, from the atmosphere to the soil, and thence to the plant through its roots.

ORGANIC MATTER.—CARBON, OXYGEN, AND HYDROGEN.—The carbon of plants is taken from the atmosphere. The leaves absorb carbonic acid, and with the aid of light wrest its carbon and oxygen asunder, setting oxygen free, and thus purifying the air, while they retain the carbon. Carbon unites with hydrogen, oxygen, and nitrogen, to make up the various tissues of the plant, the root, stem, leaf, and seed, the wood and bark, the gluten, starch, sugar, and so on. The atmosphere supplies carbon far in excess of the demands of plants. The best experiments indicate that the carbon is all, or nearly all, obtained from the air. The source of the oxygen and hydrogen is not definitely settled. It is very probable that the water absorbed through the roots is the main, if not the entire source of supply.

NITROGEN.—Our cultivated plants get the bulk of their nitrogen from the soil, through their roots. Many years of labor of the best investigators, and many thousands of dollars, have been devoted to the study of the sources of the nitrogen of plant-

stores up atmospheric nitrogen for plant-food. The nitrates in the soil, formed mostly from the decay of vegetable and animal matter, are the chief natural sources of the nitrogen of plant-food. Ammonia, which, like nitric acid, comes from vegetable debris and from manures, as well as from the air, is also used by plants. Other compounds of nitrogen, no one yet knows just what or how many, can also be assimilated by plants.

MINERAL MATTER, OR ASH.—The mineral ingredients of plants are derived exclusively from the soil. Of these, POTASH, LIME, MAGNESIA, IRON, PHOSPHORIC ACID, and SULPHURIC ACID, must be furnished to all agricultural plants, through their roots and by the soil, in order to their growth. If the available soil-supply of any one of these is deficient, the whole crop must suffer. As regards soda, silica, and chlorine, the experimental evidence is not so decisive. A small quantity of chlorine has been proven necessary for the perfection of some plants. Soda is needed in very minute quantities, if at all by crops. A little of silica is probably necessary to the perfect blossoming and ripening of grain.

To sum up in a few words: "Air and water together yield the materials out of which fully ninety to ninety-eight per cent of crops is built up. The soil has to give for their nourishment only the two to eight per cent of mineral matters, which remain as ashes when they are burned, and the one-half to two per cent of nitrogen which they also contain."

Contiguous Houses, Costing \$2,000 each.

BY S. B. REED, ARCHITECT, CORONA, LONG ISLAND, N. Y.

These designs were prepared for a block of five houses erected last year for Mr. Geo. Storms, facing one of the principal avenues at Bayside, L. I. The entire structure is 90 feet long, running north and south, and occupies half the avenue end of a village ground plot. One end section being a "corner," has a portion devoted to business purposes, the balance of the building is used exclusively as residences. They are thoroughly furnished with ranges, heaters, pipes for cold and hot water, and gas, and complete sewerage. The desirability of these buildings (and also of those in last month's *American Agriculturist*) is proved by the fact that

Fig. 2.—PLAN OF CELLARS OF CONTIGUOUS HOUSES.

food. The theory that plants avail themselves of the free nitrogen of the air, of which there are thousands of tons over every farm, must be regarded as wrong. The theory that plants in general, and the "large-leaved" plants in particular, as clover, turnips, corn, etc., obtain a good deal of combined nitrogen (ammonia and nitrates) from the air by their leaves, is hardly tenable. The gain of nitrogen from this source, seems to be very small indeed. The most of the nitrogen of our crops is got from the soil through the roots. The soil gathers some nitrogen compounds from the air, however, and it is extremely probable that it assimilates free nitrogen, and thus, in two ways,

all of them were engaged, and several occupied before they were fully completed.... **Cellars.** (fig. 2).—Height of ceilings, 7 feet. Each is well lighted, and has outside entrances from the street and from rear yards. A hall, laundry, and water-closet, are floored and otherwise finished off; the balance is unfinished, to be used as a cellar for fuel and vegetables. The Laundry has a set of stationary wash-tubs, with cold and hot water. The Water-closet has an outside door leading from the rear yard, (this is designed to obviate the necessity and unsightliness of the usual out buildings.) The Fire-places shown are left open, and have contiguous flues the whole height of the chimneys,

These flues being heated through contact with the upper fires, insures a thorough ventilation of this story.... **Elevation**, (fig. 1).—This building appears well from all directions, is imposing in out-

.... **Second Story**, (fig. 4).—Hight of ceilings, 9 feet. The divisions in this story are similar in each of the five buildings, and consist of a hall, two large and two small rooms, and the necessary

The bath-tubs and water-closets are cased with black walnut.... **Plumbing**.—To give an exact idea of the plumber's work, the specification used as a guide in its introduction is herewith given:

There must be a hopper water-closet, and a wash-tub with three apartments put in each basement. A No. 2 range, with elevated oven, and water-back; a 30-gallon oval-topped copper boiler of croton pressure strength, resting on an iron Lockwood Stand, and an 18x30-inch iron sink in each kitchen; a bath-tub, 5 ft. long, lined with planished copper; a wash-stand, with 14-inch bowl, marble-top and wall plates; a pan water-closet, with bowl, pull, and crank attachments; and a tank, 1½x1½x3 feet, lined with sheet lead, in each bath-room. All supply pipes to be of galvanized iron, of the following sizes: The main of 1½-inch, 93 feet long, laid in the cellar bottom below the foundation walls, near the rear chimneys, one end to extend outside the building for street connections. Branches of ¾-inch leading from the main supply to the tank, with secondary branches leading to the hopper-closet, wash-tubs, and sink. All other water-pipes to be of lead, as follows: For cold water leading from the tank, to the bath-tub, water-closet, and boiler; and for hot water leading from the boiler, to the sink, wash-tubs, and bath-tubs, of A ¾-inch; for connections between the water back and boiler of AA ¾-inch; and for wash-stands of A ½-inch. The water and hopper closets are to have traps of 4-inch, lead, connecting them

Fig. 1.—ELEVATION OF CONTIGUOUS HOUSES AT BAYSIDE, L. I.

line, animated in details, and nicely proportioned—the hight agreeing with its breadth; the openings, and dressings, are changed in each story to

Fig. 3.—PLAN OF FIRST FLOORS.

give diversity, the whole being well suited to its very public and prominent situation. The "Corner" building has an observatory extending above the main roofs, indicating its terminal position, and adding an agreeable feature of irregularity in the sky-lines. The Street end at the rear of the tower has a Mansard roof with two dormers; the opposite end shows a full pediment.... **First Story**, (fig. 3).—Hight of ceilings in four houses, 10 feet. The floor in the corner building is lowered 2½ feet, making that part 12½ feet in the clear. A hall, parlor, dining-room, and kitchen, are finished in each of the four houses, and a store, kitchen, and entry, in the corner building. Each of the parlor has a large hay-window, and is divided from the dining-room by sliding-doors. The Dining-Rooms have two closets each. The Kitchens are conveniently arranged with closets, ranges, boilers, and sinks. The Store is fair sized, has a double door entrance from the avenue, and has a wide stairway leading directly from it to the cellar. The Kitchen at the rear is for the use of the parties doing business in the store. The Family Entrance to the corner building is from the street at the side,

closets. The room over the store is used as a parlor. One of the small rooms in each house is fitted as a bath-room. The Stairs leading to the attics are placed above the main flights, with a door at the foot of each.... **Attic**, (fig. 5).—The Attic of the corner building is partitioned off, and finished as shown, with ceilings 9 feet high, and has an inclosed stairway leading to the observatory. The latter is 7 feet square in the clear, and is also finished. Each of the four adjoining attics are plastered on their sides, but have no partitions....

Construction.—The Excavations are made in the earth for the corner building, to the depth of 5½ feet—and for the others, 3 feet. The Foundations are of 8-inch brick work. The Frame is of sawed, seasoned timber. The Main Division Walls between the houses are decafened, by filling with pale brick and mortar, "laid flat." The Sidings are of clear pine clap-boards, laid on rolled sheathing. The Mansard Roofs for front, one end, rear, and the tower, are slated; all other roofs are tinued. The interior walls and ceilings of the two full stories, are hard-finished on two coats of brown mortar; the balance is white-finished on one coat of "laid off" brown mortar. The halls, parlors, dining-rooms, and store, have stucco cornices and centers in each, and the openings to the hay-windows are arched and moulded. Marble Mantles are put in the principal rooms, and marble shelves and stucco trusses are put in the large bed-rooms.

Fig. 4.—PLAN OF SECOND FLOORS.

Fire-place Heaters are put in the parlors, with pipes connecting them with registers in the second story.

with the soil pipe. Ventilating pipes of 2-inch tin, to lead from the 4-inch traps to above the roof, and have cone-shaped covers set 2 inches above their openings. The soil pipes to be of 4-inch iron, and lead from the second floor to the tile drains at the rear and below the cellar bottom. Waste pipes to be of 1½-inch, with traps, all of lead, leading from the bath-tub, wash-bowl, sink,

Fig. 5.—PLAN OF ATTICS.

and wash-tubs, to the soil-pipe. Brass lever "stop and waste" cocks must be put in the branch supply-pipes near the basement floors, and in the pipes leading from the tank to the boiler. A "Fuller's" Tank Regulator to be connected with the supply-pipe leading to the tank. A "Sediment" Cock must be attached to empty the boilers, with pipes leading to the waste-pipes of the sinks. Finished brass ¾ "compression" cocks, with flanges, and thimbles, must be provided for the sinks and wash-tubs, and similar cocks silver-plated, for the bath-tubs; plated swing cocks for the wash-stands. Self-acting compression cocks must be put in the connections with the hopper closets. Plugs, with chains, must be put in each wash-tub and bowl, and trap-screws put in all traps. Finally, all to be properly connected, in a substantial and workman-like manner, and warranted one year with ordinary use.

Estimate for cost of materials and labor:

Mason's materials.....	\$2,200.00
Lumber of all kinds.....	1,950.00
Slate and Tin.....	450.00
Roiled Sheathing.....	50.00
Cornices, etc., from Mill.....	250.00
Porches and Stairs with Railings.....	800.00
Hardware and Nails.....	400.00
Mantles.....	360.00
Plumbing, Gas Pipes, and Sewers.....	940.00
Doors, Sash, and Blinds.....	725.00
Cartage.....	100.00
Carpenter's labor, not included above.....	1,800.00
Painting.....	475.00
Total cost of Five Houses.....	\$10,000.00
Average cost, \$2,000 each.	

American Roadsters.

It is claimed by many advocates of the "trotting ring," that the renowned American race of roadsters or trotting horses owes its existence, or at least its excellence, to the so-called "trials of speed" in the ring, and that the interest in these trials or races is maintained by betting. It is also claimed that without the excitement of the betting all the interest in the race-course would subside; that there would be no races, no trials of speed; as a consequence there would be no demand for speedy horses, and there would be no efforts on the part of breeders to improve the race. Indeed, it is asserted that the business of breeding, whether professional or amateur, would cease to exist were races and betting abolished. It is only sufficient to broadly state this claim in this manner to show its absurdity and falsity. There is enough interest in the horse to make its improvement and increased value and usefulness, an object not only of profit, but of pleasure and excitement. There is nothing more agreeable or exciting to any one, old or young, than rapid motion. The savage and the most cultivated man alike enjoy riding upon or behind a fleet horse. So long as there are numbers of men who can afford to pay largely for their pleasures, the breeding of fast horses will ever be a profitable pursuit, and so long as men delight to skim over the road as fast as possible, there will be a demand for the best roadsters. Besides, this class of horses may be of great value in case of war, because, for attack or defence, well mounted cavalry is of the greatest moment. Decisive battles have been lost for want of good horses, and have been won by the overpowering force of well mounted cavalry. No nation possesses a better supply of horses than the United States, and the time may come when the maintenance of our excellent races of trotting horses may be of the greatest service to us. Much has been said by some few American writers, to disparage American trotters in favor of the English running horses; but not to speak of the uselessness of a galloping horse upon the road, the evidence is all in favor of the endurance, strength, and hardiness of our trotters, and against the qualities in these respects of the running horse. As a specimen of an American brood-mare, we give the above portrait with which we have been favored by Mr. Thomas Fitch, of New London, Conn. It is a copy of a photograph taken by Messrs. Schreiber, of Philadelphia. Mr. Fitch has been engaged in

breeding roadsters and family carriage horses for many years, and we have seen some fine specimens in his stables. This mare, "Lady Buckingham," was bred in Canada West, and was sired by "Tip-poo," out of a "Reindeer" mare. She has been driven faster than 2.30, but has never been trained,

both cows and horses, are pets, and remarkably gentle, as must always be the case, when the breeder is kind and gentle to them, never uses the whip, and has a natural inclination towards his occupation. This style of training is especially valuable for driving horses, in which docility, gentle-

ness, and fearlessness add so much to the value. Mr. Fitch's method of breeding is worth notice. He writes, "I never breed from a mare of less weight than 1,000 lbs., nor more than 1,150, height 15.2 to 16.1; choosing good form, color, and action. Both sire and dam should be as nearly perfect as possible; but a defect on the side of the sire is not so injurious as on the part of the dam. The dam produces and rears the colt, and she should be as near perfect as possible."—While all breeders do not hold this opinion, there is, nevertheless, much truth in it, and doubtless much injury has been caused by neglecting proper precautions in selecting mares for breeding. There has been far too

"LADY BUCKINGHAM."

although speeded occasionally. Mr. Schreiber, the well known animal photographer, when he took this picture, thought it to resemble that of "Lady Thorne" more than any other he had taken, and the resemblance is certainly very striking. The produce of this mare so far, in Mr. Fitch's hands, has been two fillies, one 5 years old, named "Pneuma," by "Young Hambletonian;" she is over 16 hands high; in color, a dark-brown, with white hind feet, and has fine action. The other, 3 years old, named "Tacheia," by Rev. M. Murray's "Live Oak," is of large size, chestnut in color,

much stress laid upon the importance of the sire and his power of overcoming defects in the dam.

The Norfolk Polled Cattle.

One of the most useful efforts of a gentleman, who has interested himself greatly in the furtherance of an improved agriculture—Mr. A. B. Allen, of New Jersey, and one of the founders of the *American Agriculturist*—has been the attempt to popularize in America the polled Norfolk cattle.

For some unaccountable reason there is a common prejudice against hornless cows. There is something in a name, and if these cows were not called "mooleys," but simply "polled" or "hornless," it is possible that the prejudice would not exist. Cattle that have no horns are more quiet, inoffensive, and comparatively harmless, and in case of animals that are to be shipped by rail, there is great economy in the freight, as a larger number of hornless animals can be carried in a car, than there can be of those with spreading horns, and there is no risk of injury from the horns of the quarrelsome beasts. Of the three varieties of polled cattle, the Galloway, the Angus, and the Norfolk, the last is

NORFOLK POLLED COW.

with white hind feet, and is also very fast. The mare is now in foal, as are all Mr. Fitch's brood-mares, to "Toronto Abdallah." Mr. Fitch has so far been very successful in breeding this class of horses for family use, devoting much care to secure a fearless and docile disposition. All his animals,

the best for the dairy; the others being excellent beef cattle. The Norfolk cattle are red, and the above engraving, a portrait from a photograph given in the *Agricultural Gazette*, London, accurately shows the form of a good specimen of this class of cows. The fine fore-quarters, deep hind-

of the running horse. As a specimen of an American brood-mare, we give the above portrait with which we have been favored by Mr. Thomas Fitch, of New London, Conn. It is a copy of a photograph taken by Messrs. Schreiber, of Philadelphia. Mr. Fitch has been engaged in

quarters, and well developed udder, give unmistakable proof of the high milking qualities of the breed. The Norfolks are an old established breed, somewhat larger than the Devons, and of a very similar color, a bright red. They are better milkers than the Devons, yielding frequently 2,800 quarts, or over 6,000 pounds of milk, between the annual calvings. There is already one herd established here, and the qualities of the breed might induce dairy-men and breeders to import these animals largely.

Among the Farmers.—No. 29.

BY ONE OF THEM.

About Auction Sales of Stock.

I have attended three remarkable sales of live-stock lately held in, or near, New York City, and think I have gained some insight into the causes of the success or failure of auction sales. The success of any sale is measured by the satisfaction given to both buyers and seller. If both are content, we may conclude that the occasion is a rare success.

When Edward Fowler, of Southampton, England, offered 24 head of Channel Island cattle for sale in New York, 3,000 miles from home, every body knew that the sale was absolutely unconditional, that there was no such thing as "bidding up" or "buying in." His auctioneer had every thing systematized—plain, clear, full catalogues, and a high platform up to which the animals could be led; they would thus stand close to the auctioneer and his assistants, and in plain view of all those present.

Peter C. Kellogg's "Combination Sale" of trotting horses was the most admirably managed affair I have ever seen or known about. Widely advertised, the stock offered was most fully and admirably catalogued; and every owner who sent a horse to the sale was pledged, over his own signature, not to permit any "bidding up" or "bidding in," or any unsubstantial bids, that every thing might be perfectly fair, and every sale absolute. The result was, a perfect freedom in bidding, as no one suspected any unfair dealing. In each of these cases, the fullest opportunity had been given to examine the stock. There was no doubt in regard to the pedigrees or ability to enter the breeding animals or their progeny in the herd register, or the trotting register, and so buyers being well informed, and confident of fair dealing, bid freely. The Jerseys sold at a higher average price than any Jersey cattle ever sold for before in this country. One heifer, and that, too, with quite a faulty udder according to my notion, brought the highest price a Jersey cow ever sold for in this country (\$620). The horses, likewise, sold at a higher average than any similar lot of horses ever before offered, "Kentucky Prince" bringing \$10,700, the highest price ever before paid for any trotting horse at auction.

Now as to the third sale. It was extensively advertised as a "Clearing Out Sale," so to speak—that is, every animal on the farm was offered, and a plausible reason for selling out was given. The animals were of pronounced excellence, and their fame had been trumpeted far and wide by newspaper writers. Buyers came hundreds of miles, ready and willing to spend their money. The cattle were in excellent condition, and though standing in their stalls, and not easily examined, while some could not be handled at all, being turned loose in a paddock, nevertheless, they made a very favorable impression. The catalogue was poor enough, being printed in a confused way, with the pedigrees wretchedly "mixed" on the inside of a country newspaper. When it came to the selling, there seemed to be no concert of management, the rabble huddled around the auctioneer and the animals, and thus forcing back those who might have been buyers. The auctioneer failed utterly to impress his audience with confidence in himself or his sincerity, or with the belief that the sale was a bona-fide one. As usual, the bids started slowly, and a noble bull was sold on the first bid for \$100, when he would have been cheap at \$400 or \$500. After this, some bull-calves were offered, being started at \$150 and \$200 on bids received by the auctioneer (?) by telegraph, and declared sold without a bid being

made upon the ground. This was a damper, and when the cows were brought in, the bidding was duller than ever; one or two were sold, when some more bids came "by telegraph" of \$200 or \$300 for calves hardly two months old. This seemed to convince the people that there was something wrong; not a few asked one another if it were not "a put up job." It stopped the bidding, and the sale was closed. The hundreds of dollars spent in advertising the sale were lost; there was a good deal of credit lost, and it is not too much to say that such a crowd will not be likely to come again.

What Makes a Successful Sale?

The essentials for securing a successful auction sale of live-stock are, therefore, as I conceive: 1st. The offer of animals of real value at a time when they are wanted. 2d. Not only advertising well, but telling buyers all they need to know in a well arranged catalogue, which must be, or at least appear to be, perfectly honest and truthful. 3d. Giving the people present at the sale the assurance that the animals are offered without reserve, and absolutely to the highest bidder.

Harnessing a Yearling Filly.

It was "Roxy's" birthday on the 12th of April, and it was celebrated by putting her in harness for the first time. The headstall, without blinders, was put on, the check-straps tightened to fit, the Dutch collar slipped upon her neck, and the saddle and breeching attached thrown upon her back. The breeching made her a little nervous, so I sent for a little sugar, which quieted her at once. In this "rig" she was led about for a few minutes; then the reins were drawn out from the saddle-rings, and she soon allowed herself to be driven about quite well, I going behind her. Then we geared her to a very light road-wagon, and she looked a little nervous, but her attention was at once taken up by the offer of sugar. She was led a few steps, and allowed to see clearly the wagon following behind her, and again sugar was offered. Soon she might be led anywhere drawing the wagon, at a walk or trot, up hill or down. I even drove her once around the house, but thinking the lesson sufficient for once, we stopped here. She was not in the least frightened from first to last, and I have not a doubt was impressed chiefly with the new experience to her sense of taste. Such an exercise repeated once in every fortnight, or even once a month, with slight variation, as she becomes familiar with her duties, and learns to stop and back at the word, will, in a short time, make her a thoroughly "broken" horse, without her even knowing it herself, she thinking only of the sugar she gets for good behavior. There is no lack of spirit in the filly, but so far, there is no show of wilfulness that does not yield to the mildest coaxing—nor any vice. It would, however, take but a very little jerking, and a cut or two from a whip, to turn her "milk of kindness" into curds, and make her as contrary as she is now pliable.

The Early Bird.

I have been watching the hens a good deal lately in the mornings, and find that the "Leghorns" are invariably out first. There will be half a dozen of these trim, dainty biddies, out for the proverbial "early worm," long before any others, except a single "Spangled Hamburg," the only one we have. Then come the "Leghorn half-breeds," then "Plymouth Rocks," while the "Cochins" and "Brahmas" do well if out within an hour after sunrise. Each season confirms me in the view that the "White Leghorns" are the most profitable of the egg-laying, non-setting breeds. I have little or no experience with "Brown Leghorns," but my neighbors complain of their fighting, and the dash of "game" blood that is in them would doubtless impart more or less of that tendency. The same thing is true of the "Silver-gray Dorkings," which have been, as is well known, crossed with "Duck-wing Games" to secure uniformity and brilliancy of plumage; the cocks are often great fighters. The "White Leghorns" I have had, seem little inclined to fight, and this is true of the "Hamburgs," yet possessing all the wide-awake, early-bird qualities of the "Games," which are certainly as active as any. I wish I

could keep them, but they require so much attention, so quickly deteriorate if not carefully and intelligently bred, and "tested," too, that I shall allow a little experience, of a few years ago, suffice.

Clover Freezing Out.

For the first time since we have lived here, we find clover, in low spots, entirely frozen out. Passing over the ground about the last of March, I saw the ground nearly bare, and lying here and there all over the surface were slender roots, nearly as large round as one's finger at the upper end, and tapering rapidly to say $\frac{1}{8}$ or $\frac{1}{16}$ of an inch at the other, and six or eight inches long. Lifting, I found two or three inches often still in the ground, and could hardly believe that they were clover-roots, until I found upon a few, some half green, minute leaves struggling for life. I remember in Hartford County, Conn., we used to have the clover winter-kill, and that it was called "freezing out," but I certainly never before saw roots drawn up fully eight inches, as was the case with my clover this year. Timothy, on the same land, was thrown out, too, so that I do not believe it could live; but the frost seems to have had no effect on the Red-top, which appears to glory in the ruin around it.

Tillage, Plowing, Harrowing, Clod Crushing, and Rolling.

American farmers are averse to doing thorough work in the matter of tillage. We want plows which turn a furrow 14 inches wide, and then we rake over the surface with a broad harrow, and put in the seed. I do not see much objection to the use of a wide furrow in plowing, yet I believe that the narrow furrows of the English and Dutch plows are decidedly better for the soil, but I have found, time and again, to my cost, that half way work in preparing a seed-bed is disastrous. Last year, I hired a piece of work done, at a time when I could not well attend to it. A rough out-lot, upon which the moist season had brought up an abundant crop of Ragweed, Wild Carrots, Yellow Clover, Evening Primrose, Running Blackberries, with Pussy Clover, and Rattle-box, and fifty other things for aught that I know, the natural product of a gravelly and neglected soil. This I hired plowed and sowed with rye. I was not there to watch it, so now the rye looks as if it had been drilled in, following the furrows. The ground had been harrowed after plowing, but not half enough. Such land should be harrowed and cross harrowed, and diagonally harrowed, until the surface soil is mellowed and knocked out of the embrace of the myriad rootlets, which fill and hold it. The stones, moved by the plow, at least those near the surface, should be brought to the top. There they protect the, at best, thin soil, from winds and frost, and the larger ones may be picked off. What there is of fine soil is settled and compacted, by the harrowing alone, so that the roots of the plants have a much better hold upon it. Besides, the harrowing exposes the roots of the sod and weeds to the action of the sun and atmosphere, to their almost certain death, which is what we desire.

This, I conceive, is the effect of thorough tillage by the harrow upon my poorest soil, and upon similar soils everywhere. If the ground is being prepared for grain and grass, these may be sown at once; then let the stones be picked off, and finally let the field be rolled, for the sake of still further compacting the soil, and leaving a surface less exposed to injury from winds and from washing.

I have rarely much use for a clod crusher, and when I have, I find that the wooden-toothed harrow of my neighbors, turned upon its back, to be the very best I ever saw. It might not do on clays or clay-loams, where baked clods, or masses of earth, packed by the plow, and half baked by the sun, cover the field and resist both the harrow and roller. These require the severe treatment of the clod crusher of the agricultural stores, which, with its disks of forks and zig-zags, has a good deal the look of a concentrated cast-iron thunderbolt. The harrow, on its back, is enough for eorn stubble, sods, bunches of weeds, etc., which dodge harrow teeth, when the implement is right side up, but can not escape the beams and braces which are drawn actually in contact with the ground.

Disk Harrows.

I am interested in investigating these just now, but I can not pronounce definitely upon their merits. I have found that when an implement actually fails to do any particular kind of work well, though excellent for other things, that very fact will suggest its name. Now the disk harrows turn a number of little furrows beautifully, each tooth working like a small plow. They crowd into the mellow earth the strawy manure, sticks, chips, and such things not too large, and cover them nicely. They cover seed well, cut an old hide-bound sod, and by a peculiar action when drawn repeatedly over it, leave it in condition to renew itself to its manifest advantage. These things, I am sure, they do quite well, but they are called "pulverizing harrows,"—and that is the very thing I am in doubt about. Do the disks pulverize as well as square steel, or iron teeth, drawn through the soil? Perhaps they do in some soils, and not in others; perhaps they do in all soils, but I doubt it. There is one argument in favor of their doing good work in this way, which can hardly be gainsayed—that is, they draw very hard—that is, most of them do. I am glad to know that there is one now made which, like the well known Geddes' harrow, and some others, by means of a flexible joint in the center, accommodates itself to inequalities of the soil.

Talks on Farm Crops.—No. 16.

By the Author of "Walks and Talks on the Farm,"
"Harris on the Pig," etc.

"I don't see," said the Doctor, "why you do not sow more Swede turnips."

"Because," said I, "Mangel-wurzels suit me better. Mangels are more nutritious than Ruta-bagas; can be made to yield a heavier crop; will keep later in the spring; do not impart any unpleasant flavor to the milk; can be sown earlier in the spring, and on a greater range of soils; are almost entirely free from attacks of insects and mildew, and, when once up, and fairly growing, will stand our hot dry weather far better than turnips."

"That is all true," said the Doctor, "but still the Ruta-baga or Swede-turnip has many qualities which ought to make it a favorite crop with you. Sometime ago, you made the remark that if you grew more cabbages than you could find a profitable market for, you had plenty of hungry customers at home that would consume all you had to spare. Your idea was to sell cabbages as long as the price would suit, and as soon as they were so cheap that it did not pay to market them, feed them out at home to your stock. That cabbages could be either sold or fed out was an argument in their favor. And, if so, then the same remarks will apply to Ruta-bagas. They often bring good prices in market. I have frequently paid 50 cents a bushel for them. And the books tell us that 1,000 bushels can be raised on an acre, and I have seen reports of crops of over 1,500 bushels per acre. Why, then, do you not raise them? Sell what you can find a market for, and feed out all you can not sell. Your mangels, of which you raise so many, can not be sold. There is no demand for them. They are good only for stock. They are not, like turnips, cabbages, carrots, parsnips, beets, etc., a table vegetable. If you raise Mangels you have only one string to your bow; with Rutabagas you have two; viz., sell when you get a fair price, and feed them when the market is glutted."

"I believe," said the Squire, "I will put in five or six acres of Ruta-bagas. They will pay far better than potatoes."

"That is so," said I, "provided you can get a good crop and sell them at a good price. But the probabilities are that you will not get a good crop."

"I would like to know why," exclaimed the Squire, "I have seen great crops of Swede turnips in Canada; our soil and climate are as good as theirs."

"True; and we can raise just as good turnips, but to do it we must adopt a better system of farming than is common in this neighborhood. Turnips require garden culture. The land must be dry, clean, rich, and mellow. Turnips require finer

tilth than beets. The seed is small, and will not grow unless deposited in nice, fine, moist, mellow soil. And at this season of the year, in our dry climate, such a seed-bed does not come by chance. We must make proper preparation for it. Instead of this, we sow turnips on land that we happen to have unoccupied. If too wet for oats, corn, or potatoes, we sow turnips, and hope for a good crop."

"Yes," said the Squire, "and I have raised a good crop of white turnips in this way that cost nothing but the seed and the pulling."

"I know it; and that is why I said you would probably not get a good crop of Swede turnips. A chance good crop is demoralizing. You hope to do the same thing again. It is a species of agricultural gambling. To raise a good crop of Swede turnips, you must give them a chance. If the season is so favorable that you can grow a crop with no preparation and little labor, there will be so many turnips in the country that they will bring little in market. It is a good crop in an unfavorable season that brings large profits."

"Let us hear how you would go to work to raise a big crop of Ruta-bagas?" said the Deacon.

"Select the best land on the farm—that in potatoes or corn last year, and plowed in the fall, would be good."

"Hold on a moment," said the Squire, "I have a piece of land that was in wheat, and seeded with clover, which failed. How would that answer?"

"If the clover failed because the land was wet, it would not answer at all."

"It is a bit of good land," said the Squire, "rather sandy and somewhat poor."

"Well, plow it up at once, and cultivate and harrow and work it until you get the sod, if there is any, all out top and torn all to pieces. The more you work it the better. Then draw on 15 loads of good, rotten manure per acre. Spread it, and harrow it thoroughly."

"But the harrow will pull it into heaps."

"If it does, spread them again, and keep on harrowing and spreading until the manure is broken up fine and mixed with the soil. It would be well to use a cultivator to more completely mix the manure with the soil and to break up all lumps. Harrow once more after the cultivator."

"And I suppose," said the Squire, with rather a sarcastic smile, "you would use the roller also?"

"Certainly, if there are any lumps, I would roll and harrow and cultivate until the land was as fine and mellow as a garden. Then plow once more, harrow and roll. Then mark out the land in rows from 2 feet to 2½ feet apart."

"Can not you be a little more definite," said the Squire. "If 2 feet is as good as 2½, why not say so?"

"It depends somewhat on the land, and still more on the kind of cultivator you use. If you have nothing better than a common corn cultivator, you had better make the rows 2½ or 3 feet apart, as the cultivator will be apt to smother the plants. But if you have a proper cultivator that will run within an inch of the young plants without throwing earth on to them, two feet is wide enough for the rows. But unless the soil is very rich, it is perhaps best to make the rows 2½ feet apart. It is less work to cultivate and hoe; and you will get larger bulbs than if sown thicker."

"What is the use of a marker," asked the Squire. "A good drill makes its own mark for the next row."

"It is not much work to mark out a few acres of land with a good one-horse marker, such as we use for marking out corn. If the land is as mellow as it should be, the teeth will make a good deep mark, two inches wide. And now I want to tell you something that is worth knowing—something which is of the first importance to the turnip grower—something which will often double the crop. In fact, I have repeatedly known it to make all the difference between success and failure. It is very important in England, but it is still more important here, owing to our dry weather and our increased liability to having the young turnip plants destroyed by the little black beetle."

"What is it?" said the Deacon. "If it will keep off the beetles I would like to know it."

"It will not keep off the beetles, but it will so stimulate the growth of the young plants that they

soon get out of danger. As soon as the plants get into 'rough leaf' the beetles do little damage. Mr. Lawes told me, thirty years ago, that if I would sow this article in the rows with the seed, he would insure me against damage from the beetle. Its effect on the growth of the young plants is marvellous.

"Its application here is comparatively new. Until within a year or two it was so high and so poor—or at least so uncertain, that a farmer could hardly afford to use it. But now we can buy it at reasonable rates, and no farmer who reads the *American Agriculturist* need be cheated. He can get a good article of guaranteed composition. I have used it for many years, and should have used it still more extensively if I had raised more turnips, and could have got a good article at anything like present prices. What we now want is a good drill that will sow this manure in the drill with the turnip seed. We have good drills that will sow it with wheat, and barley, and corn, but I do not know of a drill that will sow manure and turnip or onion seed at one operation. They have such drills in Canada, and possibly there may be such manufactured here, but I do not know of any."

"And until we have such a drill," said Charley, "it is necessary to use the marker."

"At any rate, we have not yet hit on any better plan on this farm. Mark out the rows 2½ feet apart, taking pains to have the rows not only straight, but deep and wide, and then go along the rows and carefully sow a little *superphosphate* in the mark. It is some work, and should be done by a careful man. It is a shame that we have no machine which will do it. But until we have it, we will pay, on a small scale, to do it by hand. The *superphosphate* should be previously run through a sieve, and all lumps broken fine. If damp, mix a bushel of plaster with three bushels of *superphosphate*, or if plaster is not cheap enough, use sifted coal ashes. Sow 200 lbs. to 300 lbs. of *superphosphate* per acre; then drill in the seed, running the drill along the mark where the *superphosphate* is sown. We use a hand garden drill, and sow 2 lbs. of seed per acre."

"One pound is enough," said the Deacon.

"Yes, and more than enough. A quarter of a pound per acre, will give all the plants needed, if they come up just where you want them, and the beetles let them alone. But all experience shows that it is well to sow turnips thick enough to insure a continuous string of young plants."

"If very thick," said Charley, "it will not do to let them grow much before hoeing, or they will all mat together, and be weak and spindling, and it is a good deal of work to single them out."

"You have just hit the nail right on the head. As soon as the rows can be distinguished, run a cultivator through them, and follow with the hand-hoe. It is quite a knack to hoe turnips properly and expeditiously. Our common hoes, while admirable for most purposes, are too broad, and slant too much towards you for singling out turnip plants. You want a hoe that you can push as well as pull. By heating the shank of the hoe, you can bend it out until it is nearly at right angles with the handle, or until it will push out the plants. The cultivator runs within 1 or 1½ inches of the plants, leaves very little work for the hoe, except to single them out. Strike the hoe through boldly, and this will probably leave a plant that will fall over towards the hoed space; if so, place the hoe between it and the other plants, and push out all the plants the entire width of the hoe, and cut the soil deeper and a little wider in bringing back the hoe towards you. This ought to leave another plant ready for singling out as before. A turnip plant has more roots than a beet or mangel-wurzel, and you can cut closer and deeper in hoeing turnips, than in hoeing beets or mangels. In hoeing beets, more or less of the singling out has to be done with the fingers, but turnips can be singled out with the hoe. It requires some patience and skill, and possibly some patience and faith. Hoeing turnips is like swimming—a boy who once learns the art never forgets it."

"In regard to the distance apart," said the Doctor, "I found, when I was in England, there was a tendency to thin out to a less distance apart than formerly. Those who prided themselves on growing very large roots, made the rows 2½ feet apart,

and thinned out the plants to 18 inches distant in the rows. But many farmers thought it better to have the rows two feet apart, and thin out to 12 inches in the rows. The roots are smaller, but they

Fig. 1.—ARRANGEMENT OF BINS IN GRANARY.

think they are more nutritious. In the former case you have 11,616 turnips on an acre, and in the latter 21,780 turnips on an acre. If the former averaged 5 lbs. each, which is not by any means a large turnip, there would be 29 tons per acre; and in the latter case, if the bulbs weighed 2 lbs. each, there would be 21½ tons per acre. And it is thought that 20 tons of the small roots contain more nutriment than 30 tons of the large."

"In this country we are not at all likely to thin out too much. The prevailing error is in the other direction. It seems such a pity to cut out a dozen nice plants and leave only one, that I have hard work to persuade my men, when hoeing by the day, to use the hoe boldly. If hoeing by the acre, they would soon learn to thin out severely."

"Do you mean to say," said the Squire, "that you would leave only one plant to each 15 or 18 in."

"That is exactly it; or if you do not want large roots, leave one at every 10 or 12 inches. For later use, or if sown late, it is perhaps better to thin out to 10 inches apart. I once sowed Swede turnips as late as the 4th of July, and had a good crop, and of splendid quality for the table. For feeding to stock, it is, of course, better to sow earlier—as early in June as you may be able to get the land ready."

Hints and Helps for Farmers.

BY L. D. SNOOK, YATES CO., N. Y.

GRAIN BINS.—Without proper bins for grain, much that is hard earned in the field is easily wasted in the barn. The floor of a granary should be of doublehemlock boards one inch in thickness, dressed and tongued and grooved. Sometimes it may be desirable to lay a floor of plank, and cover this with a layer of hydraulic-lime cement three-quarters of an inch in thickness. Either of

Fig. 2.—PLAN OF GRANARY.

Fig. 3.—SIMPLE BRUSH HARROW.

Fig. 3.—SIMPLE BRUSH HARROW.

These floors will be rat-proof. There should be a window in every granary, with fine wire gauze shades to exclude weevils and grain moths. Figure 2 is a

plan of a granary; figure 1 shows the mode of constructing the bins. The posts (*B, B,*) have grooves, into which the boards are slipped as the bins are filled, and they can be removed when not needed. The boards should be numbered, that they may always be properly placed. Portable steps (*E*) are very convenient when the bins are deep.

BRUSH HARROWS are cheap and useful for many purposes, such as leveling the surface of fields newly planted with corn, or potatoes; for mellowing the soil when it is crusted, and for covering light seeds. Figure 3 shows a very simple one, made of

a scantling (or a round pole) 9 feet long. Holes are bored 6 inches apart; small branches are inserted into these, and wedged tightly. Another method, seen in figure 4, is to place the brush between two planks, which are afterwards drawn

Fig. 4.—IMPROVED BRUSH HARROW

closely together with screw bolts. If it is desirable, a farmer may make a riding harrow by fastening bundles of brush to a long axle by means of wire, and affixing a seat to the axle (figure 5).

HAULING MANURE.—In Western New York, where some farmers haul out several hundred loads of

Fig. 5.—BRUSH HARROW WITH SEAT.

manure, the following plan is adopted. Two or three wagons are used, one being left in the yard to be loaded, while the other is drawn to the field and unloaded. Thus it is necessary that the unloading be done quickly. For this, the box is removed, and bottom planks (*W*, fig. 6,) with side-boards a foot wide, are provided, upon which cleats (*T, T,*) are nailed near each end to prevent splitting. A notch is cut out, as at *A*, that the board may be easily lifted from the wagon, as is shown in the engraving. With this arrangement of the wagon, one person can unload the manure, by removing the side-boards and pulling or pushing the load off in heaps upon each side with a manure hook.

STAKING A RAIL FENCE.—To stake a worm rail fence, proceed as follows: When the foundation is laid, and the fence is three rails high, stakes are to be driven in the angles close to the rails, and then fastened with a piece of annealed wire, as shown at figure 7. A few more rails are laid, and the stakes are again tied; and to finish the job, a wire should

be fastened above the top rail. In figure 8, the stakes are set and wired as the fence is built.

An English Milk Farm.

In the management of a milk dairy, the profit is made up of a number of very small items. A few of these small matters are sufficient to cast the balance upon the side of loss, instead of that of profit. It is, therefore, important that every detail in the

Fig. 6.—MANURE WAGON.

work of a milk farm should be carefully scrutinized. Only one-tenth of a cent per pound in the cost of the milk, in a year, amounts to three or four dollars per cow, and a loss or gain of one quart per cow, per day, will amount to ten dollars in the year. The objects to be gained in a milk dairy are: to keep the expenses as low as may be, and to increase the product as much as possible. Every thing tending to secure these objects, is valuable to the dairy farmer. There are few farms from the management of which we can learn so much as from some of the best conducted English milk farms. Generally the best milk farms in America are managed very much up-

on the same system, because there is no secret in selecting the best cows, or in choosing the best milk-producing food, but we do not make so much use of roots and oil-cakes as do the English farmers, and these are the cheapest and best milk producers. An outline of the management of an English dairy, which is of great interest, is given in the "London Live Stock Journal Almanac." This farm is in South Derbyshire, a limestone country, in which the grass forms the best and most nutritious pasture in the world, and with which none of our pastures can bear comparison. With this exception there is nothing in the system of which we can not avail ourselves if we wish. The cows are nearly all purchased when fresh, and sold off for fattening when failing in milk, but are not fattened on the farm. No calves are reared, except a few bred from the best milkers. The cows are well fed the year round, to keep up a regular and maximum supply of milk. In summer the feed is pasture, in the fall, the aftermath is fed, along with cabbages, until winter feeding begins. This consists of hay, brewer's grains, roots, cut straw, and 5 or 6 pounds

Fig. 7.—WIRING A FENCE.

of oil-cake, or corn-meal, per day. The roots (Swedes and Mangels) are pulped and mixed with the grains and the chaffed straw; 8 cents a bushel is paid for brewer's grains. Tares are sown in May for soiling, and if the grass is abundant, these are not fed, but are cured for winter feed. A large portion of the farm is arable, and only 40 cows are kept on the 300 acres. A large quantity of purchased food is used, but, as may be expected, very little of fertilizers is purchased. The advantage, upon milk farms, of this system of using artificial

Fig. 8.—WIRING A FENCE.

only 40 cows are kept on the 300 acres. A large quantity of purchased food is used, but, as may be expected, very little of fertilizers is purchased. The advantage, upon milk farms, of this system of using artificial

foods of the richest character, is very great, because the larger portion of them is returned in the manure, and that which is carried off in the milk is quite inconsiderable. Thus a well managed milk farm does not deteriorate in fertility, but both it and its owner grow rich together. The consumption of milk is steadily increasing, and upon those farms from which there is easy access to the large cities, their production can, by good management, be made profitable, both in its immediate returns, and in the indirect addition to the value of the land.

Plan of Stables for a Small Place.

A plan for a small stable, to accommodate a cow and two horses, with poultry-house and pig-pen annexed, is often asked for and we give one. Figure 1 is the ground plan, 31 feet long, and 18 feet wide. The central part comprises two horse stalls, 5 x 10 feet, and a loose box for a cow, 7½ x 10 feet, with a passage, in which is a feed bin, room for a fodder-cutter and feed box, and stairs to the hay loft. Over the feed box is a hay-shoot from the loft above. The poultry-house adjoins the passage, from which two doors open into it. This house is 18 x 12 feet, and has a sloping front of glazed sash. The roosts are shown in the engraving by the three bars in each apartment. The poultry-house is divided into two parts, so that one can be appropriated for young chickens and brooding hens, which is a very convenient method, and avoids the loss of a single chick. At the other end is a yard for manure, with a pig-pen at the rear. There are two openings from the stable into this yard, for the purpose of cleaning out the manure. Figure 2 shows an elevation of the building. Generally a plain structure will be desired, but, if necessary, an ornamental roof may be made, and the building finished more elaborately than is here shown. The

Fig. 1.—ELEVATION OF STABLE.

nexed, is often asked for and we give one. Figure 1 is the ground plan, 31 feet long, and 18 feet wide. The central part comprises two horse stalls, 5 x 10 feet, and a loose box for a cow, 7½ x 10 feet, with a passage, in which is a feed bin, room for a fodder-cutter and feed box, and stairs to the hay loft. Over the feed box is a hay-shoot from the loft above. The poultry-house adjoins the passage, from which two doors open into it. This house is 18 x 12 feet, and has a sloping front of glazed sash. The roosts are shown in the engraving by the three bars in each apartment. At the other end is a yard for manure, with a pig-pen at the rear. There are two openings from the stable into this yard, for the purpose of cleaning out the manure. Figure 2 shows an elevation of the building. Generally a plain structure will be desired, but, if necessary, an ornamental roof may be made, and the building finished more elaborately than is here shown. The

Fig. 2.—PLAN OF STABLE.

cost of this building may be from \$200 upwards, according to its style and the materials used.

An Injection Nozzle.

The common method of giving an injection to an animal, by means of a bladder, and a piece of elder wood, from which the pith has been removed, is sometimes injurious, and at the best is clumsy. A very neat instrument for the purpose has been

INJECTION NOZZLE.

devised by Whitman & Co., the makers of the Fountain Pump. This nozzle, shown in the accompanying illustration, is intended to be attached to

the Fountain Pump. The liquid to be injected is prepared and put into a pail, is administered in the ordinary manner, the nozzle being oiled or greased. For worms in horses the usual injections of salt and water, or those of warm water, or soapy water for inaction of the bowels, in either cows or horses, may thus be given with ease and safety.

A Simple Feed-Cooker.

"A Subscriber," sends us his method of cooking food for a few pigs, as follows. An ordinary iron kettle is provided, large enough to admit the chine of a meat barrel or tierce, and arranged with a fire-place beneath it. A number of holes are bored in the bottom of the barrel, and two strong rings are affixed to the sides. The barrel is placed upon the kettle, fitting closely inside the rim, and is filled with roots and meal. A close cover is fitted to the top, and the contents of the barrel are cooked by the steam from the kettle. The arrangement is shown in the accompanying engraving. The barrel may be lifted off when the feed is cooked, by means of a small crane and windlass, and placed upon a wheelbarrow to be carried where it is to be used.

FEED-COOKER.

Foot-Power Saws and Sawing.

For small work a hand or foot-power saw will often be found very useful. But unless a machine of this kind is kept in the very best order, the power needed to run it is so much increased that the work is too hard for either the hand or foot. Some re-

Fig. 1.—PROPER & IMPROPER PITCH OF SAW-TEETH.

marks in reference to the machine in question, and the proper method of keeping the saws in such order that they will work with ease, have been sent to us by A. I. Root, of Medina, Ohio, who has had considerable experience in the use of small wood-working machines. The sawing machine is shown at figure 6. It is furnished with a pair of feeding rolls and saws of different sizes. In using this saw, or in fact, any saw, it should be remembered that the points of the teeth only do the cutting, and that, to secure ease in working, the sides of the saw should not rub against the wood. The proper observance of this principle is the whole art of keeping a saw in order. The shape and disposal of the teeth should be such that the sharp points pare off a slice of the wood and cut an opening large enough to prevent friction upon the sides of the saw. There is a certain position in which the teeth make a smooth cut, otherwise the grain of the wood is torn and not cut, and a greater force is required to tear the fibers than to cut them smoothly. The proper and improper pitch of the teeth for a rip-saw are shown in figure 1. The center of the saw at H should bear a constant relation to the angle of each tooth, which should be on a line which is called a tangent from the circumference of the inner circle, shown at G. When a straight edge is laid against this circle, it should fall upon the under-

Fig. 2.—POOR TOOTH.

side of each tooth. Then if the distances between the points of the teeth are equal, they will all fall

side of each tooth. Then if the distances between the points of the teeth are equal, they will all fall

Fig. 3.—FILES FOR SAW.

exactly upon a line which would form the circumference of a circle concentric with the circle, G. On the other side of the diagram are some teeth which are wrong, but they are frequently seen as bad as in this specimen. A saw filed in this unequal manner will require more than double the power to drive it. When a hand or foot-power is used, the difference is sufficient to prevent the operation of the saw. For a cross-cut saw, the shape of the teeth is entirely different, but can not be considered at this time. In filing the teeth to get a sharp point, the work should all be done from the underside. If the teeth are filed at the top, much of the saw is wasted. The top is worn away in cutting the wood, and if the underside only is filed away in a proper manner, the body of the saw is cut away evenly and the circumference, shown at F, figure 1, is gradually carried towards the center until the teeth become too small, and the saw is worn out or used for smaller work. That the saw is wasted by bad filing, is shown at figure 2. By filing beneath the points of the tooth, first at A, D, would in the course of time be carried to C, E, but if filed from the top the points would in the same time be brought to B, F. It is clear if, in addition to the wear by work is added the loss by filing, that the saw will be worn out more rapidly

Fig. 4.—SELF-REGULATING SAW-SET.

than by work alone. For filing small saws, files of the shape, shown at figure 3, should be used. The angle of the file is precisely the same as that of the saw when the flat part rests upon the top of the tooth. In use it is never made to cut down, but only to preserve the shape and angles of the teeth. In

Fig. 5.—SET OF TEETH.

setting the saw only enough set should be given to clear the blade; and the set should be perfectly regular, or the work will be more difficult. A self-regulating set is shown at figure 4. The screw at

Fig. 6.—HAND-POWER SAWING-MACHINE.

the top gauges the hold upon the tooth, and by bringing the handles together every tooth is bent alike. The proper set is exhibited in figure 5, the

dotted lines showing how the teeth, *A, A*, are bent so as to be regular, and to give a certain amount of clearance for the saw. To make a small saw cut smoothly, the teeth should be finished off with an oilstone. These are made of all necessary shapes to trim out the angles and to level the points of the teeth. To smooth the edges of the teeth, lay an oilstone on the table against the saw, and turn the saw backward. For finishing fine work, small planing machines are made, one of which is shown at figure 7. These machines are made now at remarkably low prices, so that there is scarcely a workshop that can afford to be without them; while for such small work as the making of surplus honey and fruit boxes, and light crates, the hand-

Fig. 7.—LILLIPUTIAN PLANER.

saw machines and planers are indispensable. But to use them with economy and satisfaction, the owners must know how to keep them in order.

A Road Scraper.

A light road scraper would be found very valuable on every farm for repairing the private roads. It may also be used, when necessary, for running over the public road in front of the farm. The appearance of the farm is greatly improved by the neat condition of the road in front of it, and as the

A USEFUL ROAD-SCRAPER.

road is actually the property of the owner of the land by which it passes, the public having only the right of using it for traveling, it is very proper that the real owner should keep it in good condition. A light, easily made scraper is shown in the accompanying illustration. It consists of a frame of stout timber, in which the scraper is pivoted. The scraper may be 4 or 8 feet wide, as it is to be drawn by one or two horses. It is raised or depressed by the handles attached behind. To run over the road for a few minutes with such an implement, after it has been cut up in bad weather, would save much repair at other times, and thus lighten the road taxes. If the use of a road scraper were general, the roads would be in much better order, and the beauty of the country would be much increased.

PORK PACKING IN THE WEST.—From the Cincinnati Annual Price Current Report, for which we are indebted to the Superintendent, Sidney Maxwell, Esq., we glean the following as to the quantity of hog products packed in the West the past year:

No. of Hogs packed.	Average net weight.	Yield of Lard.	Cost per cwt.
6,505,446	226.4 lbs.	38.61 lbs.	\$4.99

This gives a gain of 1,401,133 in the number of hogs

packed; of 10.12 lbs. in the average weight, and of 4.53 lbs. in the yield of lard, with a decrease of 19 cents in the cost per 100 lbs. 723,368 bbls. of pork were packed, an increase of 86,101 bbls. over last year. The above relates to the winter packing only. The total quantity packed, from March 1st, 1877, to March 1st, 1878, was 9,048,566 hogs. The winter product of lard was 761,192 tierces, of 300 pounds each, and of cured meats 980,000,000 lbs.

The Beet-Sugar Question.

A new mania seems to be imminent. Agricultural journals, and others not agricultural, are everywhere agitating the subject of beet-sugar, and deluding themselves and their readers into the belief that a great industry, heretofore neglected, is about to be introduced. Circulars are being spread abroad by public-spirited individuals, pointing out how easily sugar can be made from beets, at every cider mill and cheese factory; if only the beets are grown. It is all a great mistake. We can grow the beets

fast enough, and too fast, but the manufacture of the roots into sugar is a very intricate, chemical as well as mechanical, operation, requiring the greatest skill and costly machinery. The beet contains abundant salts which interfere with the process of crystallization of the sugar, unless they are got rid of by a careful operation; besides, upon some soils, the beets contain so much of these salts as to render their manufacture into sugar impossible. It would be well for farmers to give a very cautious hearing to those who try to induce them to take stock in beet-sugar factories, and to engage in growing beets for manufacture. To grow beets for sugar is quite a different thing from growing them for feeding. In the former case only small roots are desired, averaging $2\frac{1}{2}$ to 3 pounds, as these are richer in sugar than the larger ones. Only about 8 tons per acre of these small roots can be grown; the large crops of 30 or 40 tons, so much written about, are not for the sugar business. It is very certain that farmers can make more profit in growing heavy crops of sugar-beets for stock feeding, than light crops for sugar factories, if we had these. It may become a profitable business in time, but it must be remembered that the success of the manufacture in Europe, so much talked of, is the result of nearly a century of costly and persevering effort assisted very liberally by Government aid. It can hardly be supposed, that here, where labor is dear and private enterprise must work alone, we can make an immediate success. Pioneers generally fail, and others build upon the ruins of their fortunes. Still there are always sanguine individuals who are ready to make experiments, and it is possible that through their failures the way to succeed will be learned. At present, however, it is certain that the risk of loss in the manufacture is greater than the probability of gain.

An Orange Co. (N. Y.) Dairy Barn.

The accompanying engravings are to illustrate a milk-dairy barn, belonging to J. E. S. Gardner, of

Fig. 1.—PLAN OF MAIN FLOOR.

Orange Co., N. Y. This barn is 110 feet long, 32 feet wide, 20 feet high, with a basement 9 feet high. The building is on a slope, facing west. In front is a pit for preserving brewery grains, 30 feet long,

9 deep, and 16 wide. The interior arrangements are very convenient; at figure 1 is shown the

Fig. 2.—PLAN OF BASEMENT.

main floor. There are 6 horse-stalls, 16 feet long, with a manure-shoot in the corner, leading to the manure-pit in the basement beneath; a driving-

Fig. 3.—VIEW OF ORANGE COUNTY BARN.

floor, 20 feet wide, with stairs and feed-room; a hay-mow, 72 x 32 feet, with hay-shoots leading to the feeding-floor below. At fig. 2 is a plan of the basement, in which are 36 stanchions along the center, with doors at each end; in front of the cows is an alley for feeding, 16 feet wide, through which a wagon can be driven from end to end. Behind the stanchions is a standing platform for the cows, with a drop 15 inches wide, then a walk of 3 feet, and a manure-pit 7½ feet wide and 4 feet deep, with a cement floor. In the rear are several sliding-doors, one in each bent, for removing manure. The pit for grains is covered with railroad iron and flagging. A perspective view of the barn, showing its situation, is given in figure 3.

A Milk-house for Winter and Summer.

In response to several requests we give a method

Fig. 1.—SECTION OF MILK-HOUSE.

of building a brick Milk-house, with an air-space in the walls to keep it cool in summer, and warm in winter. Figure 1 is a sectional drawing. The outside is of brick, laid lengthwise, so as to make the wall 4 inches thick; the corners are to be well bound together at each alternate row of bricks; the inner wall of lath and plaster is supported on 2 x 4-inch upright studs, or furring pieces, 16 inches apart from centers, placed edge-wise, to leave an air space of 4 inches. The laths are nailed upon these. The furring pieces rest upon the foundation of brick, bedded in cement, laid crosswise, to make an 8-inch bearing. The floor should be cov-

Fig. 2.—SECTION OF WALL.

ered with cement-concrete, 3 inches thick, level with the foundation, and a close base-board should be nailed over the plastering. Finish the plaster to the floor before nailing on the base. The studs are spiked to the beams overhead, which are laid 16 inches apart, and also to the rafters. This strengthens the building greatly, and allows the air-space of the walls to open into the roof. A ventilator, carried from the ceiling to the peak, as shown, is opened or closed by a trap-door, with a cord. The house may be 16 feet square, and 12 feet high in the clear, which will give ample room for ventilation and space for the milk of 50 to 100 cows. There should be only one window on the north side, shaded by a green blind, and kept closed. It would add greatly to the coolness of the house if the walls were covered on the outside with climbers, such as the Hop-vine, Wistaria, Virginia Creeper, or other quick-growing vines, or running roses may be used. In preference to any other roof, we would select one of red tiles, which are cooler than slate, and so absorbent that a light shower, or a slight drenching with water, with the Whitman Fountain Pump, upon a hot day, would cool the interior greatly. A section of the wall, fig. 2, shows the air-space.

A Useful Gate, not Patented.

"H. S. B." Bailey, Tenn., sends a sketch of a gate which may be made very useful for various purposes, such as separating small animals from

Fig. 1.—SELF-CLOSING GATE.

larger ones, and has the advantage that it will fasten itself when closed. The gate is made of strips one inch thick, and 3 or 4 inches wide, as shown at figure 1. The latch is fastened as shown,

by bands of hoop-iron riveted to the upper and lower corner. When the latch is lifted, the gate is raised, as shown by the dotted lines, and is held in this position by the latch resting upon a support shown at a, figure 2. In this position the gate is raised from the ground, so that small pigs or lambs may pass under, and it also swings clear of the peg driven into the ground to hold it when lowered. When the gate is swung to, and the latch strikes the post, the latch is moved from the support and drops, letting the gate down on to the ground. By driving pegs into the gate post, upon which the latch may rest, the gate may be raised to any desired height. The framework of the gate is fastened together by carriage bolts, screwed up loosely, so that the gate will work easily.

Hens and Ducks in the Fruit-yard.

Young chickens and ducklings will get a large part of their living from insects, if they have the opportunity. It is a good plan to give up the fruit-yard, or a part of the orchard, to poultry. Chickens and ducks want shade as well as sunshine, and thrive better for it during the summer. They are

always on the watch for worms and millers, and greedily devour every insect that falls from the trees. They are fond of fruit, and consume the windfalls, which harbor the insects that are so destructive to fruit. A brood of chickens left under an apple tree afflicted with Canker Worms or Caterpillars, will reduce the stock, and finally exterminate them. One of the most successful fruit-growers we are acquainted with, keeps poultry constantly under his trees. The apples and pears are fair, and he has paying crops every year.

The Value of Leached Ashes.

Experiments with leached ashes continue to work favorably, and to win friends, every year. There has been a large reduction in price to correspond with other fertilizers in the market. Formerly, they sold at 20 to 25 cts. a bushel, delivered at the landing, on tide water. Our farmers now get them at 17 cts., delivered at the same place, in quantities to suit purchasers. They have been used a great many years by the farmers and market gardeners of Long Island, and later by the same classes in the shore towns of Connecticut, and on the tobacco farms farther inland. The leached ashes used come mainly from Canada, and very largely through Oswego, whence they are shipped by canal boat without change until they are landed at the harbor near the farms where they are to be used. This refuse from the asheries contains considerable quantities of potash and phosphoric acid, which have a wonderful influence upon exhausted soils. We notice that when this fertilizer is once introduced, it retains its hold upon the confidence of cultivators, and they buy ashes every year, frequently increasing their orders. The onion-growers along the Sound make large use of leached ashes—buying sometimes by the thousand bushels. This is one of the best indications of its value for that crop. Fruit-growers are much pleased with its effect upon the growth of their trees and shrubs, and upon their productiveness. It improves the size and quality of all the small fruits. It is especially beneficial upon strawberries and grapes. The use of this fertilizer is gradually increasing among the farmers who are more remote from the harbors where the ashes are landed. Their effect is immediately visible upon old pastures and meadows, spread broadcast, as a top-dressing; but they act more satisfactorily if applied to the crops at the time of seeding down. They not only largely increase the crop with which the grass-seed is sown, but their influence is visible for many years afterwards in the increased yield of grass. A farmer who has used ashes freely for twenty years, upon a hard, worn granite soil, says they will give an increase of hay, upon a meadow newly stocked, for eight years, and then, if the field is plowed again, they will show the effect of the ashes for six years longer. He applies about 100 bushels to the acre on land that he designs to keep in meadow, and about 75 bushels to pasture land. It is particularly satisfactory as an application to the rye-crop—even in so small quantities as 20 bushels to the acre. He has reclaimed a large breadth of old fields given up to the growth of bushes, briars, and brakes, and made it a fine pasture by the rye-crop and ashes. He considers leached ashes his most efficient helper in transforming an exhausted, worn-out farm into one of great productiveness, giving a fair reward for his capital and labor.

CONNECTICUT.

A Sure Cure for Poultry Lice.

Lice are the great pest of the poultry house. Hens left to range about the farm or garden will keep clean by wallowing in the dry dust. But for a good part of the year villagers have to keep their hens in confinement, and very soon, without constant watchfulness, lice appear, and if the poultry house is near the barn, or within it, the vermin spread to the cow and horse-stables, and make trouble there. White-washing, if it were attended to every month, would be effectual, if the wash

penetrated all the cracks. But this involves a great deal of labor, and it is difficult to reach all the crevices. There is the same objection to sulphur and tobacco smoke. A few of the lice are generally left for seed after every smoking. The best remedy we have ever applied is crude petroleum, or, if more convenient, the common kerosene-oil used for lamps. This is always at hand, and a few minutes labor with the oil-can will rout the enemy. Generally one application is enough to destroy them. We apply it directly to the perches, pouring a continuous stream from the spout. The hens get this oil upon their feet and legs, and it is rubbed all over the feathers. It is penetrating, and the odor seems to be exceedingly offensive to all insects. We have had no lousy hens since the application of this remedy.

*

Use of Agricultural Papers.

I have been a constant reader of agricultural papers for thirty years and more, and have found the following benefits:—1. They are a most agreeable change from the labors of the field and the garden. Every man wants diversion of some kind, and finds it in change of occupation. Reading is amusement to a man tied up to the daily routine of the farm. His mind is stimulated by the perusal of the pages of his favorite journal, by its beautiful illustrations of animals, of flowers, and shrubs, of cottages and garden walks, of new implements, of husbandry, and by its records of the experiments of other practical farmers; he is refreshed and kept cheerful and contented by this constant communion with other tillers of the soil. 2. They add largely to our stores of knowledge. Some of the best minds in the country write habitually for these papers. Some of them have had years of training in the best scientific schools of this country and of Europe, and tell us how crops grow, what tillage does for our crops, what are the best rations for horses and working cattle, for fattening animals, and for milk cows; what fertilizers our soils need, and how this want can be most economically supplied. They are full of communications from practical farmers, in all parts of the land, giving their methods of husbandry, and the reasons for them. No man can read habitually these teachings without gaining much useful knowledge in his husbandry. 3. They save much waste upon the farm, in the purchase of seeds, fertilizers, stock, and tools. Seeds are often adulterated, sometimes with sand, but often with old seed, or seeds of weeds, which, if sown, greatly increase the cost of tillage and harvesting. The papers warn us of these adulterations, show us how to detect them, and where to purchase a pure article at fair prices. In the single item of fertilizers, any man who has occasion to use them gets back his subscription for a good agricultural paper, many times over every season. In the Connecticut Experiment Station, which is mainly a creation of agricultural journalism, there is a complete safeguard against fraudulent manures. A reading farmer can know just what he buys, and not invest in sand or swamp muck. Millions of dollars are saved to the country every year by this Institution. Manufacturers of fertilizers are compelled to sell by analysis. The best implements of tillage, and of harvesting, are brought to the knowledge of the mass of farmers through the press. If there is a fair, a plowing match, a trial of reapers or mowers, or of implements of tillage, the papers give the results in detail, and he has the data for an intelligent opinion. Inventors have shifted the burden of growing crops, and harvesting them very largely, from human hands to brute muscles. The horse cuts, cures, rakes, and stores the hay harvest. A good tool often pays for itself in a single season. The results of the large increase in the circulation of our agricultural papers are seen all over the land, in more attractive homes, in cleaner and more productive fields, in better orchards, in more abundant harvests, in a better fed, better clad, and better sheltered population. It is money in the pocket of every farmer to take an agricultural paper and read it.

CONNECTICUT.

The Ponds Suitable for Black Bass.

Numerous inquiries are received about fish ponds, especially ponds suitable for Black Bass. As these can be raised where trout can not be, the general expectation seems to be, that Black Bass will flourish in any horse-pond that does not entirely dry up in the summer. The natural habitation of this fish is the St. Lawrence basin, where it flourishes in the large lakes, and in the streams that feed them. Its favorite places of resort are upon rocky shores, and in the rough water at the foot of water-falls. It is a large, gamy fish, and wants plenty of room, and an abundance of live bait. It is an enormous feeder, and will hold its own in a well stocked lake against all other kinds of fish. It is the only fish we know of that will clear a pond of Pickerel. It requires gravel in some part of the water in which it is planted, for breeding purposes. It makes nests like the roach, in which to lay its eggs, and in the Northern States, spawns in May and June. If the gravel is not there as a natural deposit, it must be supplied artificially. Of course, all efforts to plant a fish of these habits in small, artificial ponds, stagnant during the summer, must be unsuccessful. A small pond of an acre or two, if fed by springs, or if a living stream, stocked with other fish, runs through it, may support a few Bass, and answer as an amusement. But to raise Bass for profit, we must have a large pond of twenty acres or more, or, in its absence, a stream large enough to furnish water-power for factories. These fish have been quite extensively transplanted in New England during the last twenty-five years, and the conditions of success are pretty well understood. They thrive almost uniformly in large ponds, and lakes at the head of streams, and when these become full of fish, they escape at the lower out-let and stock the streams below clear to tide-water.

The fishing not infrequently becomes better in the lower waters of the stream, than at the pond where they were planted, especially if the pond is small, shallow, or muddy. The fish, if left free, will find the breeding grounds, and conditions of life that suit them. They do best in large bodies of water, with rocky or gravelly bottom, and are in no haste to leave such localities. One or two hundred Black Bass put into such a pond or lake, will multiply rapidly, and furnish good hook fishing perpetually after the fourth year. The earliest ponds stocked in Connecticut were, Waramang Lake, in New Preston, Long Lake, at Winsted, Pocatapang, at East Hampton, and the reservoir pond at Bolton. This last pond has stocked the Willimantic, the Shetucket, and Quinebang, below, and Black Bass are frequently taken in the Shad seines near tide-water, at Greenville. Judging from this experience of pisciculturists, it is idle to plant Black Bass in small ponds of an acre or two, near the homestead.

The best thing, for one who is fond of the rod and fly, to do, is to unite with his neighbors of similar tastes, and stock the nearest lake or river where there is abundant room for Bass. It should not lessen their pleasure, to know that at the same time they are increasing the food supply of their neighbors.

CONNECTICUT.

firmest leather only, should be used. A thick belt is not always stronger than a thin one, the quality of the leather is the most important factor in the strength of the belt. The best belts are cut from the center of the hide. A belt may be made to run five years by careful use, that would otherwise be ruined in one year. A belt should run free and

easy; tight belts are soonest worn out, and they cause the bearings of the shafting to heat and wear very quickly. The lace-holes of belts, are oftener torn out by having the belts too tight, than by weakness of the leather. The lace-holes should be made with an oval punch, the length of the hole being parallel with the length of the belt. The lacing of a belt should begin at the middle, and each side should be drawn up with equal tightness. The ends should be cut exactly square, and the lines of holes parallel with the ends; the crossing of the laces should never be on the pulley side of the belt. No other manner of connecting the ends of the belts is so good as lacing; this is elastic, and runs without noise or jar over the pulleys. The friction of a belt is twice as much on wood as on iron. If the pulleys are covered with leather, the belts may be run much slacker than otherwise, and they will last one-fourth longer. When a belt slips, the inner surface should be sprinkled with a mixture of Spanish white (fine whiting) and rosin, finely powdered. If a belt becomes smeared with oil or grease, it should be coated with fuller's-earth, and the inside scraped with a sharp-edged wooden blade. Soft wood is better for pulleys than hard wood; for round belts pear-wood wheels are the best. Tighteners should only be applied to the slack side of the belt. If pulleys are a long distance apart, it will be better to have a loose pulley placed midway, and use two belts rather than have so much sag in one long belt, as this causes a flapping motion and bears too heavily on the journals. When a journal heats, it may best be cooled by placing an endless belt of flannel as near as

IBERIAN IRIS.—(*Iris Iberica*).—See "Notes from the Pines," page 222.

How to Use Driving Belts on Machines.

Now that machinery and farm engines are coming into general use, a few hints as to the best methods of choosing and working belts will be useful. There are good and bad belts, although respectable makers of belts choose the best material and manufacture it in the best manner. A good leather belt, one inch wide, should lift 1,000 lbs.; if it breaks under this strain, it is imperfect. A good belt should last at least three years, if it is protected, as it should be, from moisture. A belt that is made to run on the flesh side; will, with care, outlast four of five belts run exclusively on the hair side, providing the flesh side is stuffed with tanner's dubbing. Soft and pliable belts have three times the adhesiveness, and consequently the power, of hard stiff ones. For dry, warm places, soft, coarse leather will do good service; but for moist or damp places, the finest grained and the

possible to the heated part, and causing the lower bight of the belt to run in a vessel of cold water.

Pulleys should always be a little wider than the belt. When a belt runs over one side of a pulley, that side of the pulley is higher than the other, or the belt is shorter on that side. When a belt becomes mouldy from neglect, it should be well rubbed with a dry cloth, and then with pyroligneous acid; this acid will prevent mouldiness on belts that are used in damp places. If the laces are gnawed by rats or mice, they should be soaked in castor oil mixed with an equal quantity of tallow; no vermin will meddle with leather that has been dressed with castor oil. When a belt is found to slip, the slip will be on the larger pulley, and not on the smaller one. No belt should ever run under a tension of over 300 pounds per inch of section. Never attempt to put a belt upon a pulley while it is in motion. All these rules, except where the contrary is obvious, apply equally to rubber belts.

The Irises—The Netted Iris.

Many flowers fail of appreciation because of the ease with which they can be produced, and their abundance. Take some of our common garden Irises, for example; their flowers for variety in color and beauty of texture, are really exquisite,

tary, and of the form shown in the engraving, which is about the natural size. The color of the flowers is an indescribably rich blue, relieved by a blotch of golden yellow, the two making a contrast that is most charming; added to this beauty of color we have that of fragrance, which has been compared to that of violets, but seems to us, while equally spring-like, quite peculiar. Messrs. W. & Co. in-

figured in Oct. 1871), and a few others. Recently, through the discoveries of travelers, especially in Western Asia, the number of tulips has been considerably increased, and there are now some 50 recognized species. Within a few years European cultivators have manifested much interest in the species of tulips, and some of them are of great beauty, of the gorgeous type, while others are

THE NETTED IRIS.—(*Iris reticulata*.)

GREIG'S TULIP.—(*Tulipa Greigi*.)

but they are cheap, a large plant can be bought for 25 cents, which will give dozens of blooms, and then being perfectly hardy, it requires no care whatever. Yet examine the individual flowers, and in all that constitutes beauty, they are quite equal to some of the rare plants, such as some Orchids, the plant of which costs \$10 to start with, and which must be grown with the greatest care. Then some of the less common Irises, such as the Iberian, and the Netted, may be treated as common greenhouse or window plants, and their beauty enjoyed in advance of their time for blooming in the open air, and give the real lover of plants, often a person of moderate means, an opportunity to enjoy as much of floral beauty as can those whose wealth allows them to command the most costly of Orchids and other rare plants. By no means would we discourage the culture of Orchids and such plants, for we wish that more persons of wealth would engage in it, but we would point out to those with slender purses, that there is within their reach quite as much of intrinsic beauty as the wealthy can command. We were led to these remarks by a pot of the Netted Iris (*Iris reticulata*) sent to us this spring by Woolson & Co., Passaic, N. J., growers of hardy plants, to show us how well it forced in a common cool greenhouse. This species, about which there has been considerable confusion of names, is a native of the Crimea; it belongs to the section with bulbous roots, and has very long, narrow, and pale-green, four-sided leaves. The flowers are soli-

form us that this Iris is quite hardy with them, but being an exceedingly early bloomer, coming with the crocuses, or a little later, it may be caught by the late frosts. It forces with the greatest ease; if plants are potted in the fall, and kept in a cool cellar, or in a common frame, they may be brought to a sunny window, where they will soon come into bloom, and give pleasure not only by their rich color, but by their charming fragrance.

Species of Tulip—Greig's Tulip.

No flowers make the garden so gay in spring with brilliant glow as the Tulips, with their crimson, scarlet, orange, yellow, and other positive colors. The dealers make two principal classes, the Dwarf or Early, and the Late or Show Tulips; aside from these they have a small class of Double varieties, which for a mass of brilliant color can hardly be equalled, and the quaint, odd Parrot tulips.

The Early or dwarf varieties, including the popular *Duc Van Thol*, are derived from *Tulipa suaveolens*, of Southern Europe. The Late, Show, or Florists' tulips, have *T. Gesneriana* of Russia for their parent; the Doubles and Parrots are supposed to be crosses of these and other species. Our catalogues occasionally offer a few, not more than half a dozen all told, of distinct species, such as *Tulipa cornuta*, *T. Gesneriana*, the typical form of the Show tulip (both of these, with Parrot tulip, we

equally attractive for the delicacy of both form and color, and these plants are likely to become popular in the spring garden. The most striking of these recent introductions is Greig's Tulip, *Tulipa Greigi*, so named in honor of General Greig, President of the "Imperial Russian Horticultural Union," discovered a few years ago in Turkistan. We received, a few years ago, from the remarkable collection of Herr Max Leichtlin, of Baden Baden, Germany, a bulb of this, which has been exposed for two winters without protection, and fully confirms M. Leichtlin's account of its great hardiness, according to whom, it, when its leaves are half grown, endures a temperature of zero without injury. This specimen allows us to present an engraving, which, as we can not show color as well as form, fails to give the great brilliancy of both flower and foliage. The leaves of this are beautiful in themselves, being of a glaucous green, abundantly and distinctly blotched with rich purplish brown. The flower, which is broadly goblet-shaped, is from four to six inches in diameter; the general color is of the most vivid orange scarlet; at the base of the flower is a broad blotch, as near black as we ever find in flowers, which is bordered by a clearly defined margin of bright yellow. These colors produce a most brilliant effect, and combined with the lasting character of its bloom, will make it much sought after. Such plants are of comparatively slow increase, and it will no doubt be some few years before this tulip will be generally offered by dealers. We are occa-

sionally obliged to inform our readers that we have no plants for sale. New subscribers, not knowing this, often write for plants which we illustrate and describe; we do this, as a matter of horticultural news. In this case, we have one of the very few bulbs of the country. We may say, as to the plants illustrated and described in our pages, if the plant is not in general cultivation, we mention the particular dealer who furnished us with the specimen; if this is not given, it may be assumed that it is to be had generally of the dealers in such articles.

One Grape Vine.

THIRD ARTICLE.

In the previous two articles we have endeavored to show the manner in which a vine grows, and illustrated it by the growth of a newly planted vine, which should always, the first year, be restricted to a single shoot. We here briefly recapitulate these points, as it is important to impress them thoroughly upon the mind of the grower. We have shown that this shoot is but a repetition of the same parts—a length of stem, a swollen place, or node, at which is produced on one side a leaf, and on the other side a tendril—or a cluster of blossoms, followed by fruit. Stem, leaf, tendril (or cluster), in succession. These are all the parts on the little vine of the present season's growth, and all that there is on any vine of the growth of many years. At the axils of the leaves on the main shoot, are produced laterals, or side shoots, but these are but repetitions of the main shoot, a section of stem, a leaf and tendril, and these repeated as long as the vine continues to grow. If the vine is an old one, no matter how old, each shoot that has started this spring, will be found to be exactly like that from the newly planted vine, except at its few (3 or 4) lower nodes, instead of tendrils there will be clusters. An old vine, especially if it has been neglected, appears confusing, but examine it carefully; all that will be found is the wood of former years, which has ripened and become hard, and from this spring new shoots, precisely like those we have described. It is necessary to say a word more

About the Laterals.

When the leaf upon the shoot is well developed, there will be found at the base of its petiole (or leaf-stalk) two buds, as shown in figure 3, last month. Only one of these will start and push out a shoot, the lateral. This will be, as already stated, a repetition of the shoot from which it springs; if allowed to grow, it will take away from the nourishment of that shoot, and besides, make a profusion of needless stems and leaves. Many years ago, before the matter was well understood, it was ad-

PINCHING THE LATERALS.

vised to pull out this lateral altogether—a great mistake. If this lateral were allowed to grow, the other bud would remain dormant, and be ready for next year's growth and fruit, but if it were pulled out altogether, then the other bud would start, to the great injury of next year's fruiting of the vine. Here was a necessity for a compromise, the growing lateral must be kept within bounds, and yet not so

much checked as to cause the other bud to start. This, as briefly stated last month, is accomplished by pinching. As soon as the lateral has made two or three leaves, pinch out all but the lower one; a bud from the axil of this lower leaf will soon start, and when this has two or three leaves, again pinch out all but the lower one; if there is another start—there will be rarely more than three—pinch again. The engraving, from Fuller's excellent "Grape Culturist" (which every grape grower should have), shows this clearly. At *f* is the lateral, which has been pinched once at *a*; this has made a second start, and now needs to be pinched at *b*, and so on. We say "pinched," because at the proper time for the work, the shoots are all succulent, and the work can be done with the thumb and finger, and much more rapidly than would be supposed from the description. This is to be done on the newly planted vine in order to get as strong a main shoot as possible; it is done on the old vine to control the growth, and secure strong buds for next year's fruiting. In directing the setting of the vine in April, a stake about 6 feet high was advised; the vine, as it grows, is to be kept tied to this, but not too tightly, and when it reaches the top, let it sway about at will. A vine thus supported has no need of tendrils, and they may be pinched off when quite young and tender; in a short time they become tough and wiry; this is not important, but it saves the trouble of cutting them away at the fall pruning. The insects that will attack the young vine now, are usually large beetles and caterpillars, which should be sought for and hand-picked, as it is desirable to have every leaf whole and healthy. Examine the underside of the leaves frequently, and if, especially in a hot, moist time, slight grayish patches are found here, or on the young shoot, it is mildew, and must be checked by a free dusting of sulphur, blown from a bellows.

Notes from the Pines.

A friend kindly reminds me that "The Pines" have not been heard from thus far this year. Had I undertaken a monthly series, I should apologize, but I may as well say, for his benefit and that of our many new readers, that these notes are given when it is more convenient, and more economical of space, to condense a number of matters by writing in the first person than it is to make separate articles under the editorial "we." After the unusual winter—really for once, at the East, at least, the winter has been unusual—I expected to find more or less damage had been done. When a winter is so very mild as the last was, plants are not fairly dormant; they are in an excitable state, and when a cold snap does come (and we had several last winter comparatively cold), injury is likely to result. This spring has shown but little damage of this sort, but that was where I should least expect it,

Among the Blackberries.

The "Dorchester" badly killed; "Wilson's Early" less so, while "Kittatinny," always the hardiest, is here and there killed back for some distance. On the first, scarcely a cane is alive. The Raspberries, too, seem to be somewhat injured. But as I have made a new raspberry plantation to replace the old one, the loss is of little consequence. I have a number of peach-trees that are of southern origin, and these varieties are rarely, on this account, even tried so far north as this, yet every one of them escaped harm, and came out in full bloom.... I think that I mentioned last spring, that, after many vain trials with seeds that would not grow, I started

A Bed of Sea Kale,

by importing the roots, and was at last able to enjoy a vegetable so popular in England. When looking after it early this spring, I found that, in the hurry of fall work, the covering of manure to the bed had been omitted, and worse than that, the plants had been originally set so near the surface that the crowns had been injured and were decaying. This was a sad disappointment, but I had the roots dug up—enormous roots they were; the decay was confined to the crowns, and all sound be-

low. These roots were cut into four-inch pieces, and put into the sand of a propagating bench. It was surprising to see how freely they formed buds and roots, and there was soon Sea Kale enough to make a large plantation. On the whole, I do not regret the mishap, as no doubt I should have been unwilling to sacrifice this spring's crop from a few stools, in order to propagate a larger quantity of a plant that is very acceptable in early spring, before asparagus comes, and which may be had very early by a little forcing, by covering the beds with hot manure. There are many who regard

The Wild Dandelion,

as gathered from the meadows and road-sides, as the most acceptable of spring "greens." It has a rather pronounced bitterness, which, to some, suggests medicinal qualities, and it is eaten by them with a notion that it is "healthy," which I have no doubt the Dandelion generally is, but whether it is *healthful* or not, I never cared to inquire. Having, like Japhet (or was it Jacob?), studied the "rudimans" over a mortar and pestle, I have always preferred my food and medicine on different dishes, and have sternly insisted that tomatoes were not, as alleged, medicinal, for if they were, I would not eat them.—But this is a digression.—To all who like dandelions, let me advise them to cultivate them. Sow "Vilmorin's Improved" at once, and give them about 18 inches apart each way, or in two-foot rows, a foot apart in the row. Next spring there will be dandelions, each one of which will be as large as half a dozen wild ones, and a "mess" can be cut in five minutes that it would take a boy—allowing for a boy's digressions—half a day to hunt up here and there. Then as to quality there is no comparison; grown in a manured soil, and not having to struggle with the grass, they are vastly more tender, while the often too distinct bitterness of the wild plant is subdued to a remarkable degree, and is really acceptable—though I trust not "healthy." Several years ago you illustrated the

"Common Moss Pink,"

Phlox subulata, which, in its ordinary pink form, is one of the plants met with in old gardens, but like many other good old things, is now less frequently planted than its merits warrant. The white variety (in European catalogues, under the incorrect name *Phlox nivea*, and also *P. Nelsoni*) is more rare, and more striking. Getting a bit of it some years ago, we went on dividing it from year to year, thinking so good a thing would be wanted for exchanges, and found last year that we had a large lot on hand. Not wishing to throw so good a thing away, it was put—of all places—in the vegetable garden, a row 200 feet long. This spring it had formed a bed some three feet wide, and of the above named length, and it was "a sight to behold." Seen from a little distance in the sun, it out-dazzled a snow-bank for brilliant whiteness, while by one standing close to it, could not see a leaf for the continuous sheet of flowers. Let those interested in cemetery planting make a note of the *White Moss Pink*.... Several years ago I had one of the first plants of

Iberian Iris, *Iris Iberica*,

that were brought to this country; when it bloomed I had a drawing of it made for "Hearth and Home," judging from my single plant, I thought that the European illustrations of the same were needlessly exaggerated. The flower, as it was, seemed to me fine enough and large enough, without going beyond nature. The original plant has now grown into a large, well-established clump, and its flowers this spring out-do in size any of the European cuts that I thought so much beyond the truth. If you still have that engraving, I wish you would publish it [see page 220.—ED.], that it may make this strangely beautiful, and perfectly hardy, plant better known. It is no exaggeration to say that some of the flowers are twice as large as that from which the engraving was taken, which shows that hardy plants are only seen at their best when thoroughly established. The upper, erect, divisions of the flower are nearly pure white, with occasional veins, while the lower ones are thickly lined with a peculiar purplish-brown, and each with a large purple spot, so dark that it is well-nigh black. Then the whole flower

has a peculiar crape-like texture that is most pleasing. The low stature of the foliage, not over 6 inches, with the enormous size of the flower, make it an admirable plant, whether for the early spring border, or for forcing.....Was there ever such

A Show of Fruit Blossoms

as now? Whatever may have happened to the peach trees just south of us, about here—12 miles from New York—the country is all a gay garden. Old orchards, fit only for fire-wood and breeding-grounds for the Tent-caterpillar, are “things of beauty and a joy for”—a week. Apples, pears, plums, cherries, and the few peaches, all, like Sophy Squeer’s sensibilities, are in “full blow.” The abundant blooming is not confined to fruit-trees, but the ornamental flowering shrubs appear to participate in the profuse inflorescence. The only exception to this, so far as I have noticed, is the Forsythias—sometimes called “Golden-bell,” usually one of the most free as well as one of our earliest spring shrubs; this made the poorest show I can recollect. For an early shrub, of rather low growth,

Thunberg’s Spiræa, *Spiræa Thunbergii*,

is to be especially commended; it grows 3 or 4 feet high, and has a most graceful form; its flowers are like very minute roses, of the purest white; these are produced in clusters of three, all over the bush, and make each slender, curving branch a garland of itself. When out of flower, the foliage is pleasing, the leaves being small and of a light green. It flowers in April, and earlier than any other Spiræa with which I am acquainted. All these qualities combine to make this Spiræa one of the best.... What a pity that the bloom of the

Double-Flowering Fruit Trees,

such as the double peaches, cherries, etc., is of such short duration. They are of great beauty while they last, but one does not care to give room, for a whole year, to a tree that gives returns for only a week, or less. I have a scarlet, double peach, the finest thing of the kind I have seen, that makes a grand show for a few days, but it already takes up too much room.

The Fruiting of Wistaria.

I notice that an English journal quotes our friend Thomas Meehan, of the “Gardeners’ Monthly,” as authority for the statement that the Chinese Wistaria fruits only when trained as a pillar, and that when allowed to ramble at will, this vine is always barren. This is such a strange statement, that I think Mr. Meehan must have been misquoted. In recalling the fruiting Wistarias that I have known, I find that they have been among the most neglected. I pass one almost daily, which rambles over a veranda, and up to a roof, which probably never felt the touch of a knife, much less was trained to a pillar, or to anything else, yet it hung so full of pods that I called the attention of a seed-dealer to it, and he obtained the stock.

GARDEN THIEVES.—No kind of robbery is more annoying than that of plants and fruit. In most parts of this country, the taking of flowers and fruit is not looked upon as actual robbery, and unless there is a special law, as there is in some States, the depredator can only be prosecuted for “trespass,” and the prosecutor has to establish the fact that a certain amount of damage in money, has been sustained. One may have a flower which is to him of a value that can not be expressed in money, or his tree may for the first time bear a single pear, worth to the owner more than a bushel of similar fruit in the market, yet the matter-of-fact judge, will charge the matter-of-fact jury to find damages to the market value of the articles “trespassed” upon. In a recent suit in England, two scamps, who had stolen Snowdrops and other bulbs from a garden, were sentenced to seven years of penal servitude each. A most sensible judge was on the bench, who, finding that the thieves had before served three and eighteen months for similar offences, and were not cured, concluded that it was of no use to be lenient with them, but gave them seven years each! “Most worthy judge!”

BY FAITH ROCHESTER.

Combinations of Flavors.

A friend who has availed herself of unusual facilities for studying French cookery, has given me some of the results of her inquiries and experiments. In Professor Blot’s book we were told to use a “sprig” of this and a “pinch” of that, with an indefiniteness quite puzzling to the inexperienced. I have seen recipes for flavoring, which were poor guides for beginners, or indeed for most housekeepers, because the proportions were all given in ounces and fractions of an ounce. One wishing to follow them, and having no scales, might possibly buy the exact quantities separately and mix them afterwards. But my friend has it all reduced to teaspoonfuls and tablespoonfuls, of the medium size, and made just level full. She says her preparations are those recommended by the most celebrated French cooks, only they give them by weight, and she has made them easier for our use by reducing them to level spoonfuls. A larger or smaller amount may be made at one time by doubling or halving the proportions. Perhaps it is best to begin with a small quantity.

The *American Agriculturist* gave, a while ago, directions for drying and preserving various sweet herbs, as powders, kept covered in bottles or cans. Powdered herbs and ground spices are those used in these flavoring combinations, and after mixing, they should be kept from the air in the same manner. They are used in soups, stews, hashes, etc.

Flavoring Mixture for Soups.

Four tablespoonfuls each of Parsley, Sweet Marjoram, Winter Savory, Lemon Thyme, Sweet Basil; all dried and rubbed to a coarse powder; also one tablespoonful each of Thyme, and Bay Leaf; one teaspoonful, each, of Marjoram and Rosemary.

Flavoring for Meat Hash and Force-meat.

One tablespoonful each of Black Pepper, Cayenne Pepper; two tablespoonfuls each of Cloves, and of Nutmeg. Keep this mixture dry and closed from the air. In using it, take about the proportion of one part of this flavoring mixture to four parts of Salt—a tablespoonful of the spiced salt for each pound of chopped meat.

Keeping Meat in Hot Weather.

Great is the convenience of a good refrigerator! But many of us, who live in the country, have to get along without such a convenience. Farmers’ families, who often depend upon the butcher’s meat-cart for supplies of fresh meat, are annoyed by the bother and the waste that comes of getting more beef or mutton on hand than they can conveniently use up before it becomes tainted. The most foolish waste, is to eat more of it than you need, with the idea of “saving it;” the doctor’s bill that may result from over-loading the digestive organs is not so good a show of economy, as the fresh eggs you might coax from the hens by feeding them any excess of meat. The meat should first be wiped clean and dry. Some sprinkle it well in all parts with salt. Others use black pepper plentifully (washing and wiping it well before using it to remove the pepper or salt), and then hang it in the coolest place possible—some in the well, others in a cellar. Perhaps the best precaution is to wrap it in a dry cloth, and cover it with charcoal-dust. Some say that wood ashes will answer about as well as charcoal, but I only know the virtues of charcoal by experience. I have found that charcoal will even remove a slight degree of taint. I am told that mutton is improved, as well as preserved, for a short time, by wrapping it in a cloth wet with vinegar, and laying it on the bottom of a dry cellar. All kinds of meat, including fish and fowl, may be preserved in brine for a longer or shorter time.

Drawing Lessons at Home.

A lady in Washington Territory writes me, asking some advice about teaching her children to draw.

She says they live in the midst of beautiful scenery, and they want to hang pictures of it somewhere besides on “Memory’s walls.” Prof. Huxley thinks that every child who is to be good for anything in art or science, or in anything, except the merest drudgery, ought to learn to draw; not to make fine pictures, perhaps, but to be able to sketch with some degree of exactness and quickness. He says that this requires no especial talent, for anybody who can learn to write can learn to draw. I think he is right. I think, too, that a knowledge of drawing adds much to one’s happiness through life, even if the art is seldom practised, in enabling us better to appreciate the beauties of Nature in all her forms. But I must be practical. The Kindergarten method is, to practise straight lines for a considerable time, beginning with half-inch lines, and making them gradually longer, first vertical lines, then horizontal, then oblique. This is intended for young children between three and seven years of age. It is good practice at any age, but I should never confine a child to it if it is found to be dull or tiresome. All careful practice with pen or pencil helps toward drawing. Train the fingers to careful copying, and the eye to exact measurements and comparisons. But if a child wants to make pictures, let it begin at once to copy them. It is well to use the common drawing-cards if one can get them conveniently, but any simple, well-printed pictures will do. There are plenty of them in the Little Readers, and other school books; and in such papers as the *American Agriculturist*, the cuts are very clear and beautiful. But little should be attempted at first—just a dog’s head, or a small bird, or a tree. Only one pencil is necessary at first, and of course the best is the best, but use whatever you can get, if Faber’s drawing pencils are not within reach. The best number for a single pencil is Faber’s 3. If the scenery is so charming that the children want to attempt copying it at once, let them try. They will probably see too much, or too great a diversity of detail, covering too large a picture. Teach them to cut out little pictures from the large landscape before them—a single rock with the weeds growing about it, or a solitary tree, or clump of trees. If they try this before they have copied considerable, they should often examine good engravings to see how the strong points are brought out, how different kinds of foliage are reproduced, and to learn what there is unsatisfactory in their own attempts.

An Improvement in Family Circulars.

A year or two ago I described the latest and best invention then known, for promoting sociability among scattered members of a family—the family circular, regular in its rounds, and without apparent beginning or end. One member sends it to another, and that one to the next in order, this one to the next, and so on. As it goes around in regular order, each one adds a fresh letter of his own, and taking out the letter of the one to whom he sends the budget; so that no one gets his own letters back again, but each one gets fresh news from all of the others at each round. In the Yankee family where this idea originated, they now have a new wrinkle. It is this: Each one is supplied with the same kind of paper, having a margin next to the fold; this margin is left blank. Then the letters taken out are preserved and bound in volumes to be handed down in the family. As Thomas always sends the budget to Richard, and Richard to Henry, of course Thomas keeps all of Richard’s letters, and Richard keeps Henry’s. This was proposed for adoption in our family, but one member protests that her letters are so flat, stale, and unprofitable, that she does not want them preserved. I fancy that the bright-eyed boy, whose baby antics are so lovingly chronicled in those letters, might, some years hence, differ with her opinion of the letters which drop out into my desk month after month. When I was in my teens, I spent many afternoons in my father’s garret, rummaging an old barrel of family letters, written half a century before, which seemed to me the most interesting reading I could find. A member of our “family circle” sends me in the last circular the following recipe.

Scalloped Veal.

The rule is the same as for scalloped oysters, and

may be used for cooking any kind of cold meat, and when crackers can not conveniently be had, a good dish may be made of it, by substituting bread crumbs for cracker crumbs. Put a layer of Cracker Crumbs in the bottom of a pudding dish. Wet this with Milk. Cover with a layer of finely chopped Roast Veal. Season the Meat with Salt and Pepper (and other flavoring if you choose), and scatter bits of Butter over it. Then put a layer of Cracker Crumbs wet with Milk, another of Seasoned Meat, and so on alternately, finishing with a layer of Crackers, mixed with a Beaten Egg. Cover, and place it in the oven for about half an hour. Then remove the cover, and allow it to bake a nice brown. This recipe is highly recommended as an excellent way for warming over almost any kind of cold meat.

A sister, who makes doughnuts (I never do), offers me the following recipe for

Raised Doughnuts.

One pint of New Milk, four teaspoonfuls of Sugar, one half cup of Yeast, and a little Salt. Stir thick with Flour, and let it rise over night. In the morning add as little Flour as will make the dough thick enough to roll out about an inch thick. Cut in squares of an inch and a half. As you drop them into the hot fat, stretch them out longer, and fry them thoroughly. They are (said to be) excellent with coffee for breakfast. Lard and suet, in equal proportions, *boiling hot*, is said to be better for frying cakes than either alone.

Ginger-Snaps.

Boil together one pint of Molasses (Sorghum is excellent for this), one teacup of Shortening (some consider Beef Suet the "snappiest"), a pinch of Salt, a tablespoonful of Ginger. Let it *really boil* for about two minutes, then set aside to cool. When cool, add two level teaspoonfuls of Soda, and beat all together thoroughly. Add Flour to make a dough as soft as you can roll out very thin. Cut into shapes, and bake in an oven not too hot, as they scorch very easily.

Care of Children's Feet.

I sympathize much with country-bred children in their scorn of the notions of city-bred children about going bare-foot in warm summer weather. "It will make the feet grow large!" Thus the little feet, that ought to grow in proportion as the rest of the body grows, are kept in shoes that fit as snugly as possible, hence when the body reaches maturity it is really deformed, because the little feet dressed in "number two," are not proportioned to the figure of medium height and weight. The Chinese plan is the same, only more so. The use of tight corsets is on the same principle of false art. So is the flat-board used by the "Flat-head" Indians to "improve" the natural shape of the head. I am making no plea now for undressed feet, but I would protest against tight shoes for anybody—least of all for growing children. I know of children who have corns on their feet in consequence of this abuse. Children should not wear shoes that hurt them. A little girl, who turns in her toes when walking, acquired the habit by wearing, when three years old, a shoe that so hurt her that she could only walk easily by turning in her toes. Corns on the bottom of the feet are often caused by shoes with protruding pegs, or hard buaches in the thread or leather, which press into the sole of the foot.

A Screen at the House.

It is especially the case in sparsely settled portions of the country, that the house is placed quite near the public road. This is done to avoid a sense of loneliness, and to allow the inmates a glimpse of the few passers by, that they may not feel quite isolated. It generally happens that this advantage, as it is regarded, is offset by the exposure of the rear of the house, the back-door, and the back-door yard, to the gaze of all who pass, and it becomes desirable to shut off this view of the premises by a screen, which is necessary also, to allow the inmates to pass to the dairy-house, wood-shed, or other out-buildings, unobserved. Houses, where it can be afforded, are often provided with screens of lattice-work,

of two-inch slats, crossing one another, with a hot-board below, and cornice above, which are invariably painted white, while the lattice itself is green. Such a screen, while well enough in a village, is quite too artificial and conspicuous for a country home. The best screen for the country, whether for shutting out the view, or for the shel-

SCREEN FOR A BACK YARD.

ter it affords, is a living one of evergreen trees. This, however, can not be had at once—time is required to produce it, and while this is growing some other may be supplied. Mr. L. D. Snook, of Yates Co., N. Y., sends us a design for a screen, which may be used as a permanent one, or to serve until one of evergreens has reached high enough to take its place. This, shown in the engraving, has posts, 7 or 8 feet high, which are connected by a cap-piece of boards, cut as there shown, and strands of galvanized iron wire (No. 12 or 14), are passed from post to post, every 12 or 18 inches, according to the kind of plant to be used. One of the best plants for such a screen is a rampant growing grape-vine, such as the "Clinton," or "Taylor," and until this gets established, some annuals, such as Morning-glories, or such quick-growing plants as the Maderia-vine may be used.

A Warning to Every Housekeeper—

Including husband as well as wife—is the account published last month (page 169) of the deaths, at Newport, R. I., of six persons in a family of eight, all occurring in rapid succession. The important portion of this account, is the almost absolute tracing of this mortality to its cause—utter and shocking neglect to remove the wastes of the bodies of those eight persons. Here, in the famed city of Newport—the resort of wealthy pleasure seekers, and the permanent residence of a community widely known for its intelligence and refinement—was a state of affairs which could not be found in the poorest "huddle" of holes and huts, that answers for houses to the lowest of all our tribes of savages, the Digger Indians. This condition was not due to poverty, but, let us hope, to ignorance rather than indifference. There are some subjects that we would prefer not to write upon, but when, as in this case, it is one not only involving health, but life, we feel it a duty to our readers, to call things by their plain names, and to ask them to put aside all squeamishness, while we beg them to look to the condition of their closets and privy-vaults. There are occasional exceptions, but we know that, take the country through, outside of villages and cities, where there is public provision for carrying off fecal matters, this is the one weak point in our domestic arrangements, and a disgrace to our civilization. Several years ago we made a carriage

journey of several days, with a party of well known pomologists, through one of the most noted fruit-growing districts in the country. A region not only famed for the variety and excellence of its fruits, and the beauty of its rural scenery, but also for the refinement and hospitality of its people. Everything conspired to make the visit in all respects most charming—save one. A large share of our enjoyment was neutralized by the horrid condition of the outbuildings—a few at private places were bad enough, but those at the three or four hotels where we were guests, were of a kind and in a condition which need not be described. Were some enemy to human health, comfort, and decency, to offer a prize for the very worst affair of this kind that human ingenuity could devise, we are quite sure that one of these hotels would win it, though the competition among themselves would be close. We do not mention this fruit-growing district as exceptionally bad, but as an instance of a neglect of sanitary matters in a community where we should least expect to find it. If such can occur in the very oldest settlements of generally well-to-do people, we may expect newer localities, where men are struggling to make a home, to be even worse. Diphtheria, as in the Newport case, is a disease less frequently traced to such causes than Typhoid, and other low forms of fever, Scarlet-fever, etc. That *any* disease can originate from neglect of the out-building, should alarm the whole community. We frequently read in the papers, that "the funeral was attended by the most substantial and influential citizens from miles around," and that "the sermon was most impressive, and well calculated to comfort the afflicted family," but these, and similar obituary notices, are often quite incomplete for the lack of the statement—"the privy-vault and sink-drain remain as heretofore." It is probable that there would be less of this neglect, were it not that the subject is commonly regarded as *taboo*—one not to be mentioned. "Water-closet" is tolerated, but "privy" shocks many very nice people, who will hear absolute profanity without protest. In this case we do not mean "water-closets," but *privies*, and we say that, take them throughout the country, from top to bottom, shore to shore, they are a disgrace to a people called "civilized," not only in the matter of decency and comfort, but in the vastly more important one of health; and when we hear of certain deaths as "mysterious dispensations of Providence," we feel that it would be much more to the point to call them "God's protest against the violation of His natural laws"—laws which many brutes observe more closely than do many men. The ex-

CHANGING A COMMON VAULT TO AN EARTH-CLOSET.

istence of this danger is absolutely inexcusable, as it can be avoided, almost without trouble and without cost. Now, before weather becomes settled at mid-summer heat, every common privy should be substituted by, or converted into, an "Earth-Closet."

Dry Earth, not Sand,

but good loamy soil, the stiffer the better, and perfectly dry, is all that is needed to destroy every offensive odor, and every unhealthful emanation. Earth-Closets, or "Commodore," are very convenient, and are commended to those who can afford them. They may be placed in any out-building, in any vacant closet or other room in the house, and for invalids and delicate persons, are the greatest imaginable comfort. But to secure all the benefits of dry earth, these are not necessary. An Earth-

Closet consists of a receptacle to hold the deposit, a place to hold dry earth, and a mechanical contrivance that, by pulling a handle, will allow a portion of dry earth to fall upon and cover the deposit. Now a soap box will answer to hold the deposit, another soap box will hold the dry earth, and a scoop (an empty fruit-can, if nothing better), will answer in place of the machinery for dropping the earth. These articles, if bought, need not cost 25 cents; but they, or something that will serve, may be picked up on almost any farm. Having these, if one can not arrange them with reference to a seat, in a convenient manner, he must be quite lacking in tact. This outfit will be quite as efficacious as the most costly "Commode" ever made, in every respect, save one—some persons will be so indifferent, lazy, or obstinate, that they will neglect to apply the earth. This is a matter which must be insisted upon. A contrivance of this kind may be put in a place partitioned off in the wood-shed or other building, and one should also be made at the barn for the farm hands. If the receptacle is small, it should be made the business of some one to empty it daily, throwing the contents upon the manure heap. Several inquire whether the "night-soil" is not thus injured for use as manure. Not perceptibly, if placed upon the manure heap; it is only when it has been kept mixed with dry earth for a long time, and in a dry place, that it is dissipated. But this is of not the least consequence. The value of the night-soil, of a whole family for all time, is not to be offset against a single fit of sickness, to say nothing of a death. Many will find it convenient to convert their present out-building into an earth-closet, and as a hint to this end we give the engraving preceding, from a drawing by our correspondent, Mr. L. D. Snook, Yates Co., N. Y. The old vault is to be first filled up, and the building may stand in its original location, or elsewhere, as may be most convenient. As, when properly managed, no odor whatever is given off, the structure may be placed as near the house as desirable. In the engraving a portion of the house is removed to show the arrangement of the interior. A strongly made box is provided, of such a size as will pass easily under the seats. Two joists are laid down to support wooden rollers, with iron pins for journals, upon which the box may run, and if large, the box should have ring-bolts, to allow a horse to be hitched to it when carried away to be emptied, in which case it is well to provide it with runners. If not too heavy, it may be moved by two men, with the aid of loose rollers. The engraving sufficiently explains itself.

Gathering the Dry Earth.

In a dry spell, scrape up the dry surface earth, from the garden or plowed field, or use road dust if not sandy. By capillary attraction the surface earth is never completely dry. Harrow a space thoroughly, and throw the dry surface earth upon a platform of boards laid down for the purpose. The hot sun will soon make it completely dry; cart it in before night-fall, or if it must be left over night, cover it from the dew with boards or other material. Store in a dry place. It is well to collect enough to last a year, and pass it through a screen to remove stones and lumps. One more point to be remembered. Coal ashes are quite as efficient an absorbent as dry earth, and may be conveniently used, especially in winter. Finally, let the master of the house (or the mistress) insist upon two things—that the scoop and dry earth shall be used, and that no slops of any kind shall be poured into the receptacle. Chamber slops are of sufficient value for it to pay to carry them daily to the manure heap.

Household Recipes.

The following come from housekeepers of experience and judgment, who have thoroughly tested and approve them.

"BOSTON" BROWN BREAD.—One pint each of Indian and Rye Meal; $\frac{1}{2}$ cup of Molasses; $\frac{1}{2}$ pint Milk or Water; 1 teaspoonful Soda; 1 teaspoonful Salt. Steam three hours, and then place in the oven and bake until well browned.

GIRSY PUDDING.—Cut stale sponge-cake into thin slices, spread them with currant jelly or preserves, put two pieces together like sandwiches. Fill a dish with these; make a soft custard, pour over the cake while hot, and let cool before serving.

POP-OVERS.—1 pt. Flour; 1 pt. Milk; 2 Eggs. Eggs beaten to a froth, mix quickly, and bake in hot buttered cups. Serve with hot sauce.

COFFEE CAKE.—One cup very strong Coffee; 1 cup Butter; 2 cups brown Sugar; 3 Eggs; $\frac{1}{2}$ pint Flour; $\frac{1}{2}$ teaspoonful "Royal Baking Powder," (or $\frac{1}{2}$ teaspoonful of Soda, and 1 do. of C. Tartar); 1 cup stoned Raisins; $\frac{1}{2}$ cup chopped Citron; 1 teaspoonful of Nutmeg, and one of Alspice; $\frac{1}{2}$ cup of sweet Milk. This will make two good-sized loaves.

CITRON CAKE.— $\frac{1}{2}$ cup Butter; 2 cups Sugar; 6 Eggs; 1 teaspoonful "Royal Baking Powder," (or $\frac{1}{2}$ teaspoonful of Soda, and $\frac{1}{2}$ do. Cream of Tartar); $\frac{1}{2}$ pint Flour; 1 cup Citron, cut in thin slices. Rub the butter and sugar to a smooth cream, add the eggs two at a time, beating 5 minutes between each addition. Sift the flour and baking powder, add it to the butter and sugar, with the citron.

CRULLERS.—1 quart Flour; $\frac{1}{2}$ cup Lard and Butter in equal parts; 1 cup Sugar; $\frac{1}{2}$ teaspoonful of "Baking Powder" (or Soda $\frac{1}{2}$ teaspoonful, Cream Tartar 1 teaspoonful); $\frac{1}{2}$ pint Milk; 2 Eggs. Flavor with Nutmeg. Sift flour, sugar, and powder together, rub in the lard and butter, and add the beaten eggs and milk. Mix to a dough and fry.

WASHINGTON CAKE.—St. Louis, 1780.—2 cups of Butter; 3 cups Sugar; 4 cups Flour; 2 teaspoonfuls of "Royal Baking Powder"; 5 Eggs; 1 cup Milk; 1 cup Stoned Raisins; $\frac{1}{2}$ cup Currants; $\frac{1}{2}$ cup chopped Citron. Flavor with Nutmeg and Cinnamon, one teaspoonful each.

SPONGE-CAKE.—6 Eggs; 3 cups powdered Sugar; 4 cups sifted Flour; 1 teaspoonful Soda; 2 of C. Tartar; 1 cup cold Water, a pinch of Salt.

BOYS & GIRLS' COLUMNS.

The Young Microscopist's Club.

Now that you have learned to notice little matters, you will see many things that you have passed by without even a thought. On the leaves of various trees, and other plants, you will often find swellings, and sometimes they will be "broken out" as if they had a bad skin-disease. While some of these are mere irregular swellings, others are singularly regular and some quite beautiful. These are really galls, as those swellings on plants, caused by an insect within them, are called. The "Oak-Apples," which almost every youngster knows, are very large galls, caused by various little gall-flies.

These Leaf-Galls

are sometimes produced by a small mite, sometimes a plant louse, or one of the two-winged or four-winged flies.

Fig. 1.—"NAIL-GALLS" ON LEAF.

upon this nest that the swelling makes for it; in time the creature makes its growth, and comes out in its perfect state, like the parent that laid the egg. You will find

On the Grape-Vine,

almost anywhere, one or more kinds of leaf-galls. What is very curious, the galls produced by the eggs of different insects, mites, etc., will cause the leaf to form—on the very same plant, galls quite unlike in appearance; indeed you might tell them apart by feeling them only. Figure 1 shows a bit of a grape-vine leaf, with what are called "Nail Galls." One of these is shown cut open, with the larva inside, in figure 2; this, when ready,

would come out a little gnat-like fly. In figure 3 is a bit of another grape-leaf, with pretty scolloped galls, the

Fig. 2.

Fig. 3.—PHYLLOXERA GALLS.

work of a louse, that minute, but very destructive creature which you must have read of.

The Dreaded Phylloxera,

which has quite ruined some of the vineyards of Europe. There are two "types," or styles, of this louse, one of which—the most injurious—attacks the roots of the vine, and this one which attacks only the leaves. I have been asked to say something about

"The" Hen Louse.

Unfortunately for the fowls, I can't describe "the" Hen Louse, for there are so many of them—half a dozen or more. Here is a portrait, figure 4, of one of the easiest to find, as it is one of the largest, being nearly a line or $\frac{1}{12}$ -inch long. Unless special care is taken, little chicks, when they are first hatched, are sadly afflicted; and the feathers on the head are all alive with them. It is well to remember that lard or oil will kill them. Not only common fowls, but all other domestic birds, including the delicate pets, such as the canary, and the wild birds from the largest to the smallest, are infested by parasites—as animals and plants that live upon other animals and plants are called. When any unusual birds are shot, it is well to examine them for these. Lice are true insects, but mites are also found on birds.

Fig. 4.—HEN-LOUSE.

If you have house-plants in a warm dry room, the leaves of such plants as Camellias may become brownish, and the leaves of more delicate plants may appear blotched, and begin to drop. And after searching for the cause, if you take some leaves and go to an experienced gardener, he will very likely say, after a glance at the leaves,

"Pooh, Red-Spider, My Young Friend."

You go home and look for spiders, and find none. In hot summer days, when it is dry as well as hot, the leaves of the pear-tree, so bright and fresh but awhile ago, become brownish and look in a bad way, and some one who knows about trees is asked to tell what is the matter. He will very likely say, "Ah, Red-Spider—you have it bad."—You look all around and find no "Red," or any other spiders. You will be told that the Lindens and some other shade trees, have "The Red-Spider." If you are much among gardeners you will learn from their talk that this "Red-Spider" is an important fellow, and wonder why, with all the mischief that is charged upon it, you do not find this remarkable "Red-Spider." There are several reasons, the principal being that

It is Not Usually "Red," and is Not a "Spider."

these joined to the fact that it is so very small as to be barely visible, are good reasons why you failed to find it. So much is said of it by gardeners that persons who do not know it, expect to see some large creature. It is not a proper spider. The spiders have their abdomen, or belly portion, joined to the body proper by a narrow portion (like a waist), but this insect is in one piece; hence is classed as a mite, and belongs to the spinning mites, as it makes a web finer than that of any spider. Then they are of different colors on different plants, and at different ages, and are greenish, brown, rust-colored, and sometimes bright red; for this reason the name is misleading. When full-grown, this mite is about half a line (or $\frac{1}{24}$ of an inch) long, but they are usually much

Fig. 5.—RED SPIDER—YOUNG.

smaller. They are found mostly on the under sides of the leaves, where they spin a web of wonderful fineness, beneath which they live, feeding on the juices of the leaves, and breed in a warm and dry place with great rapidity. So small are they, and so often some other color than red, that those who do not know what to look for, fail to see them, and the little pests go on with their destructive work. Our Microscope will show them very plainly. Figure 5 is a young and imperfect male Red Spider, with only six legs; figure 6 gives the perfect and full-grown male, with eight legs, and two very strong projections, or jaws, at the head. The perfect female is about the shape of figure 5, but has eight very hairy legs.

Fig. 6.—RED SPIDER—PERFECT.

How to Kill the Red-Spider.

It does not like water, and in greenhouses where the air can be kept moist, and the leaves often showered, it does not make much headway, but in a dry and hot room the leaves must be lightly sprinkled with sulphur.

Using the Diaphragm.

You will remember that we advised not to use the Diaphragm ordinary—that is, the little plate with a hole in it—but to turn it outside the glasses. But when you wish to examine a small point only, as an insect's foot, turn in the diaphragm, adjust the focal distance of the lenses from the object carefully, and then, with a proper light, it will bring out very small things wonderfully plain—even things you would not notice in looking through the glasses ordinarily.... Among the many insect objects none have more general interest than the

Foot of the Common House Fly,

which is shown in figure 7, rather larger than you will be able to see it with our Microscope, although you can make out the parts very clearly with that. Besides a pair of strong claws, the foot has two broad plates, which are thickly covered with minute hairs. It is well known that the fly can walk upon smooth glass, and can also walk on the ceiling with its body down; it has been stated that its feet are provided with something that acts like a boy's sneaker, that allows it to hold itself in these positions, but it is now found that these little hairs on the feet give out

Fig. 7.—FLY'S FOOT.

a sticky matter, and that this mainly, if not wholly, enables it to walk on smooth surfaces and upside down.

The Mouth Parts of the Honey Bee

form another interesting object, but it will require some care to lay it out properly. It is generally supposed that the bee draws up its honey from flowers by means of a snicker, such as the moths and butterflies have; but this is not the case, they have no proboscis proper, but a kind of very long tongue, and they take up the juices by lapping. In figure 8 the long dark portion in the center (A) is the "tongue" (as it is generally called, though it is really a long lip). This is not a tube, but solid and closely covered with short hairs, and can be extended to considerable length. Each side of this is a lip (B), the two forming a case for the "tongue;" outside of these are two long jaws (C), and outside of these two shorter jaws (D). When not in use, these parts can be contracted, and drawn in and occupy but little space.

The Eyes of Many Insects

are exceedingly beautiful, especially those related to the bees and flies. Not having a bee or any such insect at

hand, I have borrowed a picture of a bee's eyes (fig. 9) to show you what to look for. These eyes are called

Fig. 8.—BEE'S TONGUE.

"compound eyes," being made up of a great number of minute separate eyes, or "ocelli." In the engraving the right-hand eye is entire, while that on the left-hand has a portion of the ocelli removed, and some of them placed singly to show their shape. I am not sure that you can see these so plainly in the bee, but I know that you can in the Dragon flies, or "Darning Needles,"

Fig. 9.—EYES OF A BEE.

which will soon be abundant, and which, by the way, contrary to the popular notion, are quite harmless. The number of these "ocelli" in the two compound eyes of a common house-fly is said to be about 4,000, and in some Dragon flies as many as 24,000.... Some have asked me to give them instructions for

Mounting Objects.

There are several methods of mounting; some objects are put up dry; others in Canada Balsam, or Dammar Varnish, or Glycerine Jelly, and others still in some kind of preserving liquid. For some kinds of mounting the cost of materials and apparatus is too great, and the amount of care and skill required are more than quite young people are likely to have, and those sufficiently advanced in microscopic matters to undertake the more difficult kinds of mounting, are likely to have a work on the microscope in which such matters are given more in full than could be possible in these articles. Some of the methods of mounting are so difficult as to be an art of themselves, but the one in use for the greater number of objects is

Mounting in Canada Balsam,

and that, too, is the simplest of all. Still this requires some care, and to describe it properly will require more room than I can give to it this month; besides I need to experiment a little to see if I can make some of the operations more simple. It is well not to be in a hurry about mounting; you who never before used a microscope can have hardly become skillful enough to make neat preparations for mounting. Yet I will try what we can do.

Aunt Sue's Puzzle-Box.

ANAGRAMS.

1. In sacred bible.
2. Alas! no convert. I.
3. Agents main me.
4. I am in a soft net.
5. I tanned! not I!
6. O flagrant coin.
7. Into iron grate.
8. O fine fat cat.

NIP.

SQUARE WORD.

1. A foreign city.
2. Pretty in a landscape.
3. To happen.
4. Moral perceptions.
5. In every forest.
6. XERYION.

BIBLICAL DOUBLE ACROSTIC.

The initials give a noted city, and the finals a famous man of olden time.—1. Part of a house. 2. A city of Sharon. 3. The wife of a Patriarch. 4. A word signifying "My husband." 5. An inflammable fluid. 6. A musical instrument. 7. The mother of a Prophet. ISOLA.

CROSS WORD.

My first is in Washington but not in Lee,
My next is in grasshopper but not in bee,
My third is in meadow but not in hay,
My fourth is in week but not in day,
My fifth is in sadness but not in glee,
My sixth is in wasp but not in flea,
My seventh is in ton but not in pound,
My eighth is in square but not in round,
My ninth is in yesterday but not in now,
My tenth is in when but not in how,
My eleventh is in walk but not in run,
My twelfth is in cannon but not in gun,
My thirteenth is in Krupp, who makes big guns,
Which weigh a very great number of tons.
My whole engages the attention
Of monarch and of peasant;
I should not like to have it here,
I know 'would not be pleasant.

JOHN W. WHEATLEY.

NUMERICAL ENIGMAS.

1. I am composed of 26 letters:
My 11, 6, 5, 19, is used for a summons.
My 10, 17, 4, 15, is used by the shoemaker.
My 9, 8, 14, 24, 5, is burdened.
My 25, 24, 26, 2, is what we all need.
My 16, 12, 1, 14, 24, 5, is inelegant.
My 7, 3, 13, 22, is to thrust.
My 23, 21, 20, 18, is the same as the last.
My whole is a well known proverb. W. H. S. F.

GEOGRAPHICAL ENIGMA.

I am composed of 28 letters:
My 16, 18, 2, 12, is a territory.
My 4, 10, 17, 7, is a river in Asia.
My 24, 26, 6, 5, 3, 15, is a river in New York.
My 11, 14, 12, 8, 19, 4, 9, 21, 4, 4, is a river in Pennsylvania.
My 22, 1, 25, 5, 23, 13, is a lake in one of the Middle States.
My 20, 12, 10, 5, 4, 27, 23, 3, is the Capital of a Southern State.

My whole is where this enigma was made. F. W. PARKS.

SYNCOPE AND TRANSPOSITION.

(In each of the following sentences are two blanks; one letter is to be taken from the word that fills the first blank, and the rest of the letters are to be transposed, to make a word that shall fill the second blank and make sense of the sentence; e. g.—"The men took their ——— with them to ——— the premises." Fill the first blank with the word "wives," syncope the letter s, and transpose the remainder ["wive"] into the word "view" for the second blank.)

1. The ——— was escorted by a ———. (The remainder not transposed.)
2. I ate a boiled ——— at ———.
3. The ——— was pleased with ——— visit.
4. I proffered the ———, but I had to give a pretty good ——— for it.
5. The ——— was situated at the end of the ———.
6. Sometimes it is not ——— to "No."
7. I ——— that the plant is a species of ———.
8. They managed to ——— the officers after fighting their ———.

Thanks for letters, puzzles, etc., to Lee, G. W. Evans, S. W. W., Juliet P., "Word-Builders" (I am glad that so many have enjoyed the game), J. H. B., B. A. Metz, Frank, Minnie B. B. (answers should always accompany puzzles sent for publication), Freddie L. Hurley, I. E. W., Marion, and others, whose favors I hope to answer at some future time.

ANSWERS must be postponed to next month.—Ed.

Aunt Sue's Chats.

ANNIE F. C.—Those "Shawl-covers" are very convenient for lady-travelers, and I will "give directions"

Fig. 1.—PART OF SHAWL-COVER.

for one with pleasure. You will need one yard and a half of "green Russia linen-twilled crash," 18 inches wide (it costs about 22c. a yard), three 6c. pieces of alpaca skirt-braid (either black or brown as you prefer), and about three cents' worth of ivoryed to match the braid. Cut the main piece for the bag, 22 inches long, leaving the width of the material entire. Cut two circular pieces 9 inches in diameter, and 4 pieces like figure 3—eight inches by two—for the handles. Sew the braids on to the main piece, of which figure 1 shows an end, leaving nearly an inch space between them, and turn a hem about an inch and a half wide, on both ends. Make the three button-holes (see fig. 5). Work the feather-stitch be-

Fig. 2.—FEATHER-STITCH.

tween the braids, as shown in figure 1 (and more plainly in figure 2. The "feather-stitch" was very thoroughly described and shown in the May No. of the *American Agriculturist*, 1877). You can mark the vandykes with

Fig. 3.—PIECE FOR HANDLE.

the corner of a square card. Double the braid and sew it around the edges of the two circular pieces (like welting). Sew on the braid, and work the feather-stitch as in figure 4. Sew the salvages of the main piece around each (as in figure 3), then bind them around with the braid, and sew them on to the bag, as shown in figure 5. They are called "Shawl-Covers," but are used as satchels,

Fig. 4.—END OF SHAWL-COVER.

and you will be astonished to find how comprehensive and convenient they are. Figure 5 shows the cover complete.

F. B. H. asks, "Who were the Seven Sleepers, and how long did they sleep?"—A widely diffused legend of the early days of Christianity has it, that seven noble Christian youths of Ephesus, named Dionysius, Maximilian, John, Malchus, Serapion, Martinian, and Constantine, to

Fig. 5.—SHAWL-COVER FINISHED.

escape the persecutions of the Emperor Diocletian (A.D. 283-304)—some say of the Emperor Decius (A.D. 249-251) (both emperors persecuted the Christians)—took refuge in a cavern, where they were walled up to perish, but were made to fall asleep, and miraculously kept so for 230 years. When they awoke, they ventured down to Ephesus, and were amazed to find Christianity honored everywhere. It is said, that when they died their bodies were

Fig. 3. PLAN OF GARDENER BIRD'S GARDEN. (See p. 228.)

taken to Marseilles, where a huge stone coffin is still shown as containing their remains in the Church of St. Victor, once a Benedictine Convent of the eleventh century. (What happened to the remains between A.D. 500

and 1000, history doesn't tell.) Reference is made to the same legend in the Koran, where it is told in "the Chapter of the Cave." The names of the sleepers there given, are Shazzernooos, Jemlika, Debbernoos, Kephestet-jooos, Meshilina, Mernoos, and Mislina. The Turks think all these names of good omen, and put them on their buildings by way of fire insurance, and on swords to prevent them from breaking. Ketmehr, the dog, which is said to have accompanied them and to have stood guard over them the entire time, is also said to have been admitted to Heaven, together with the ram of Abraham's sacrifice, Balaam's ass—the ass upon which our Lord rode into Jerusalem, and the mare on which Mohammed mounted to Paradise. The story of Rip Van Winkle, by Washington Irving, no doubt grew out of the above legend.

The Doctor's Correspondence.

When in answer to several letters I promised to tell you

About the Telephone,

I knew that I had undertaken a difficult job. I last month told you something about sound, and how it could be sent to a distance. Sound is produced by the air, which, though we can not see, we can weigh, measure, and study it. But in the Telephone we have to do with electricity—something that can not be weighed and measured as air can be. Much is known about the effects of electricity, but just what it is and many other things about it, even the most learned are in the dark. In describing such difficult things as the Telephone to young people, we can only tell what is done, for it would take a volume to tell all that is known about matters concerned in it. You know a little about

One Kind of Electricity;

when you stroke the cat's back on a cold dry day, you hear a crackling, and in the dark see sparks. You have known the same kind of electricity—on the grandest scale, when you see the flashes of lightning and hear the thunder. Nearly all of you have seen the telegraph poles, and the wires stretching from one to another, and know in a general sort of way that messages are sent along that wire somehow by electricity. The electricity used in the telegraph is not the same kind that we get by rubbing the cat's back, or that crackles, when you suddenly pull off your silk neck-tie on a cold clear night, but a very quiet and manageable kind. If you are near a telegraph station, you may have seen several glass jars partly filled with a liquid in which are some bright pieces of metal. These jars together are called a Battery, and here is produced the electricity to work the telegraph. If we have a plate of copper, and another of zinc, and place them in a jar in which is some Sulphuric Acid (Oil of Vitriol), made weak with 12 or more times as much water, the acid will soon begin to dissolve the zinc, but it will not appear to trouble the copper very much. Now let us attach a wire to each, the zinc and the copper (and for this purpose it is best to use wire wound with fine cotton thread), as in figure 1. If we bring the two ends, A, B, of this wire together in the dark, a tiny spark may be seen; if we put between the ends of these wires a bit of very fine platinum wire, the platinum will become so hot that you can not touch it, perhaps hot enough to light a match, or even red-hot. If you join the ends of the copper wire, and bring a compass near it, you will find the needle pays no attention to the North Star, but will place itself at right angles to the wire. All these show that these copper wires are unlike ordinary wire, that something is happening in them, and if you think that this has something to do with the action of the acid on the zinc, you will be very near right. But here is something still more curious. Take

Fig. 1.—BATTERY.

Fig. 2.—ELECTRO-MAGNET.

A Bar of Soft Iron,

and having one of the wires, A, B, long enough, coil it around the iron bar, and then unite the two ends as before. Figure 2 shows this arrangement. Nothing will appear to have happened to the bar, but if you bring a compass needle near to one end of it you will see that it is very much disturbed, and will dance about, as you move it from side to side, in the wildest manner. Now

bring a shingle nail, a small key, or other bit of iron, to the end of this bar; when very near it will jump towards it, and be held there with considerable force. Very likely the nail, or key, already on the bar, will hold up another, and perhaps several. You have no doubt seen a magnet—boys often have their knife-blades magnetized, and they amuse themselves by picking up needles, tacks, etc.—and you will at once say that this iron bar has been made a magnet, or has been magnetized. You may think that now you have a very nice large magnet that will be very amusing to have, so you unhook your wires, A, B, and down goes your nail, or key. You apply the bar to it—it behaves nothing like a magnet, and cares nothing at all about the nail. Hook together your wires again, and you have the bar as good a magnet as before. Bring together, and separate the wires, A, B, as rapidly or as often as you please, and the bar changes from no magnet and to a magnet every time. Now

We must have Names

for these curious acts, and the articles used to produce them. The glass jar with the two metals and acid is called a "Galvanic Battery," and frequently, only a "Battery." To increase the power, 10, 50, or more, may be joined, and it is still a battery. In practice, the metals are so arranged that the action only goes on when the battery is in actual use, and this is a great saving of materials. You have seen that, when the wires, A, B, are

Fig. 3.—MAGNET, COIL, AND COMPASS NEEDLE.

joined, something happens in them—it appears as if something was passing through the wire from the zinc to the copper, and it is very convenient to call it a "current." Whatever it is, it is a form of electricity, and to distinguish it from "frictional electricity," produced by rubbing other things besides the cat's fur, it is called "Galvanic Electricity." As it passes along a wire, that is called a conductor, and the ends of the two wires, whether that may be a foot or 100 miles long, are the poles. Here is one point I wish you especially to recollect: the wire was coiled around the bar of soft iron, and when the current passed through the wire, it did not touch the iron at all, as the thread around it prevented, so no electricity passed into the bar, but only around it—yet this bar behaved in a most unusual manner, it picking up nails, etc., and it was for the time a magnet. There are many cases in which an electrical action in one body, causes a similar action in a body near by. If you will recollect that the wire coiled around the bar induced it to act like a magnet, you will not forget the philosopher's name for it—as they call it *induction*, that is, magnetism—which is still another form of electricity, is induced in the bar of soft iron.

Recollect about Induction,

for it is a most important matter, as upon it depends the working of the Telegraph as well as the Telephone. But you know that some magnets stay active, and not like this iron bar, come and go. If we prepare a very strong "Electro-magnet," as this kind, like the iron bar is called, and then properly rub it against a bar of steel, that steel will become a magnet, and remain so. This may be a small bar like a needle, or a large one, a foot or more long. If we hang the needle by a very fine hair, or stick it through a bit of cork and float it on water, one end will point north, and the other south; the end that points north is the north pole, and the other the south pole of the magnet—names applied to a magnet of any size. If the magnetic bar is straight, its north and south pole are far apart; if bent up like the letter U, it is called a horse-shoe magnet, and its poles, though close together, are still north and south. Now, suppose you have a bar magnet, and a coil of wire, as in figure 3; pass the magnet within the coil, and immediately there will be a disturbance set up in the wire; a compass needle, if surrounded by the wire, will at once dance about and take a position, and when the magnet is removed from the coil, the needle will go back to its former place, and as often as this is repeated, just so often will the compass be disturbed. If the coil were a sufficiently large one, made of a very long wire, and the bar magnet very strong, we would take away the compass needle and bring the two ends of the wire of the coil near together; then, on passing the magnet into the coil, we should get a spark! Now you have this wire acting just as the wire did in No. 1, when a current of electricity was passing through it. You have seen that a current of electricity passing through a coil of

covered wire, can induce magnetism in a bar of soft iron placed within the coil, and in this last case, a permanent—or steel-bar magnet can induce electricity when placed within a similar coil of covered wire.

Most Wonderful, Indeed,

is this matter of induction; and I have given some space to telling you about it, as, until it was discovered, it was not possible to have either Telegraph or Telephone—and it is not possible to understand the Telephone, unless you have a general notion of this. More than this—it shows how closely magnetism and electricity are related, as we see that either can produce the other. In the next paper I hope to get to the Telephone itself, so keep in mind this talk about induction. THE DOCTOR.

About some very Curious Birds.

Those of you who live in the country with your eyes open—many, and not young persons altogether, are practically blind, for though they have eyes, they see but little that goes on about them—can find much to interest them in watching the ways of birds. Indeed, those who live in villages and towns can enjoy something of this, but the birds that will stay about houses are fewer than in places where there are woods and shrubs. It is very curious to examine some birds' nests when built, and still more interesting to watch the birds when building. If you would observe them at work, you must be very patient, and keep very still. When the birds find that you do not intend to harm them, they will go on with their work. But if you pounce in among them, as if to say, "Here I am! I want to see you work, now go ahead!" you will see nothing at all. Take a seat, keep quiet, and wait. Such a bringing of bits, such a talking it over, and such a time generally as many birds make over nest building, is well worth watching. Then, when nests are finished, what a wide difference! Some, a mere hollow in the sand, or among the grass, hardly cost any labor; then others are rough sticks, with a little grass or other soft material upon which the eggs are to rest. How different are these from the carefully woven nest of the common Robin, with its foundation of coarse straw and weeds, all finely plastered, and then lined with moss and soft material. The Robin's nest is a coarse affair when compared with that of the little Humming Bird, built of soft down from the ferns, and so carefully covered by lichens, all neatly glued on, that it looks so like a lichen (or "moss") covered knot, as to be but rarely discovered. These nests are all interesting, but among our birds the Oriole, or Golden Robin, shows the greatest ingenuity. It makes a long bag, which is woven of the strong bark of weeds, of strings, ravelings, or any other such material as it can find, and doesn't object to

examining the various styles of nests, and will wonder, as many others have done, why some birds get along with very little trouble in preparing their nests, and others take the greatest pains in making them.

But as curious and pains-taking as the nests of some of our birds are, what shall we say to a bird which builds

these bowers are merely pleasure halls. The birds and their Bower are shown in figure 1. But as strange as this is, what will you say to a bird that not only builds a bower or hut, but makes a garden in front of it! The European gardening journals that have come of late, have accounts of a remarkable style of gardening—done

Fig. 1.—THE BOWER BIRDS OF AUSTRALIA.

a house just for the fun of it—not to be used as a nest, but just to frolic in! It seems so strange a story that we should find it difficult to believe it, had not several naturalists given an account of these Bower Birds of Australia, and their structures been taken to Europe. Strong grasses are stuck up in such a manner that they meet at the top, stones being put around to hold them in place. As these houses are not for use, but for sport, the birds

by birds. An Italian naturalist, who has been exploring and collecting new and rare plants in New Guinea—which you know is an island just north of Australia, and not far below the Equator—brought home specimens of a new plant, an Orchid, and gives an account of the curious use made of its stems by the natives—that is, the feathered natives. You all may not know that among the family of plants called Orchids, are some of the most showy and curious of all plants; they are much valued by cultivators, and some of those in tropical countries grow upon the branches of trees, and never in the ground. The Gardener Bird is related to the Bird of Paradise, but is not, like that, a brilliant bird, it having brown plumage, and is about the size of a dove. The bird chooses a level place, where there is the stem of a shrub about the size of a common walking-stick. Around this it builds up a cone of moss, to make a central pillar about two feet high. Then twigs are placed all around, one end resting on this pillar, and the other on the ground, all at regular distances, to make a hut, as seen in figure 2, about three feet across. These twigs are all of a new Orchid discovered by Signor Bescari, the naturalist, which remain alive for a long time. Having built its house, and of course left an opening for a door, this bird does what the natives of the island have not learned to do, it immediately goes to work to fix up its front yard, or make what the writer calls a garden. It brings nice, clean moss, and places it carefully in front, and partly around the house, taking care to remove every stick and stone. When the lawn is ready, like a good gardener, the bird lays out its flower-beds; but it has not quite learned all about gardening, and does not cultivate, but it picks all the bright flowers, and brilliant berries, and other fruits, and places them in groups upon its turf of moss. When these fade, they are taken away and replaced by fresh ones. The traveler evidently took more notice of plants than of birds, as there are several things he omits to tell that we should like to know; he does not tell us about the nest, though he speaks of this as "the home" of the bird, and that the flowers and fruits are gifts brought by the male bird to please its mate. He says that the natives call the bird *Buruk Gurea*, which means "master-bird," and that they never destroy the nests, even if in the way. The bird imitates the songs and screams of other birds, and in that way often mislead hunters. It is, at any rate, a most curious bird, and we hope that some one who visits its country will tell us more about it. The plan of the house and garden are shown in figure 3, given on page 227. The small circle is the central pillar of moss; the outer circle is the stems that form the hut; the outer line shows the extent of the garden of moss, and the spots between this and the house, show the groups of flowers and fruits.

Fig. 2.—THE GARDENER BIRDS OF NEW GUINEA.

a bit of lace edging, or other finery that it may come across; this nest it hangs to a slender twig, where it is far out of the reach of boys, who know it as the "Hang-bird's nest." All these affairs built by our birds, are for use; they are places in which the eggs are to be laid, and young ones reared. You will be much interested in

decorate them with gay feathers and leaves, and what is still more strange, they bring bones and shells from a long distance, merely to beautify the place. Here the birds meet and, according to the accounts, have a great time in romping and mating, though sometimes the males have serious fights. Their nests are built in the trees;

PERSONS ordering Catalogues or goods from Messrs. JORDAN, MARSH & CO., Boston, Mass., will please mention having seen the advertisement in this paper.

Stockbridge Manures

"Manure for the Wants of the crops."
"Feed the Plant and the Plant will Feed You."
"Cultivate More and Cultivate Better."
"Stockbridge Manures give Large Crops at Small Cost."

Originated by Prof. STOCKBRIDGE, Professor of Agriculture in the **MASS. AGRICULTURAL COLLEGE.**

A special manure is made for each Farm and Garden Crop, containing the **Plant-Food** which each particular Plant requires. These manures were used on more than 10,000 acres in 1877, and with Great Success.

Send for Pamphlet for 1878, mailed free.

MANUFACTURED ONLY BY

W. H. BOWKER & CO.,
3 Park Place, New York.
Boston, 43 Chatham Street.

TURNIP—(For 1-6 Acre, 1 Bag,)..... \$5.50

This will produce at the rate of 400 to 600 bushels per acre, according to soil, season, and kind cultivated. Weight of manure, 250 pounds.

CABBAGE—(For 1-8 Acre, 1 Bag,)..... \$5.00

This will produce at the rate of 8 to 10 tons per acre, according to soil and season. Weight of manure, 200 pounds.

TOBACCO—(For 1 Acre, 10 Bags,)..... \$50.00

This will produce from 1,500 to 2,000 pounds leaf, according to soil and season. Weight of manure, 2,000 pounds. Many farmers apply 15 bags to the acre and find it profitable to do so.

HUNGARIAN or MILLET—(For 1 Acre, 2 Bags,)..... \$14.00

This is to produce from 2 to 3 tons per acre, according to soil and season. Weight of manure, 450 pounds. From 3 to 4 tons of Hungarian have been raised to the acre, and is considered equal to the best English hay. Farmers who have light, dry soil, not adapted to hay, but on which Hungarian thrives best, should plant this crop. It may be sown from the middle of June to the middle of August.

From 20 to 40 per cent of customary outlays for Paints, Roofing, etc., can be saved.

H. W. JOHNS. ASBESTOS LIQUID PAINTS.

ADRIANCE REAPER AT WORK.

ADRIANCE PLATT & CO.,

Manufacturers of Buckeye Mowers and Reapers, and the Adriance Reaper,

165 Greenwich St. (near Courtlandt St.), N. Y.

Manufactory, Poughkeepsie, N. Y.

The ADRIANCE is a light, strong, simple, efficient REAPER, which will work well in all kinds and conditions of grain, and combines more good points than can be found in any other. It has a folding platform, and is in all respects worthy to rank with the Buckeye Mower.

The BUCKEYE has for 21 years held its position as the LEADING MOWER and REAPER OF THE WORLD, because it is superior to all others in the principles of its construction. It is the only machine which has given entire satisfaction to the farmer; its AVERAGE DURABILITY has been MORE THAN DOUBLE that of others, and the COST OF KEEPING IT IN REPAIR LESS THAN ONE-HALF.—Prices Reduced to the lowest point at which the high standard of excellence in material and workmanship can be maintained. Descriptive Circulars forwarded by mail.

GREENE TWEED & CO., 18 Park Place, New York.

SPRING STEEL TOOTH Horse Rakes.

Highest Award. Medal of Honor at the Centennial and Vienna Exhibitions. **THE CHAMPIONS OF THE WORLD.**
No Cogs or Ratchets, Easiest Hand or Horse Dumping. Purchasers prefer them to all others for Durability and Efficiency. Fully guaranteed; so no risk is incurred in ordering from us. Responsible Agents wanted, where we have none.

Send Stamp for Catalogues of Rakes, Threshing Machines, &c.
WHEELER & MELICK CO., ALBANY, N. Y.

The Peerless Thresher and Cleaner—Clover Huller and Cleaner—Straw-Preserving Rye Threshers—Railway and Lever Powers—The Howland Feed Mill—Grain Fans and Corn Shellers. Our machines are guaranteed to work well, and have received the highest testimonials and cannot be excelled.

B. GILL & SON,
Trenton Agricultural Works, Trenton, N. J.

DOUBLE HARPOON HORSE HAY-FORK.

BEST IN THE WORLD.

Descriptive Catalogue sent free.

Pennock Manufacturing Company,
KENNETT SQUARE, Chester Co., Pa.

BARNES' REVOLVING HAY RAKES,

Superior to any in the market. Price \$3.00.

ARCHER WHEEL RAKE.

Highest award after two days field trial at Centennial. Price \$30.

The Prize Churn, from \$5.00 up. Address
A. B. COHU, 197 Water St., New York.

AMERICAN AGRICULTURIST.
ORANGE JUDD COMPANY, Publishers, 245 Broadway, N. Y.
ANNUAL SUBSCRIPTION Terms (always in advance):
\$1.60 each for single copies: Four copies, \$1.30 each: Ten
copies, \$1.20 each: Twenty copies and upward, \$1.10 each.
These rates include Postage, in each case, which is pre-paid
by the Publishers. Papers are addressed to each name.

The full Descriptions and Illustrations of the Premiums, with various Notes and Explanations, were published in 8 extra pages of our October number, which can not be repeated for want of space. Any one not having that number, can have one mailed, post-paid, for 10 cents; or a Premium Sheet only, will be mailed to any address without charge.

PREMIUM Explanatory Notes. N. B.

Read and carefully Note the following Items: The Table herewith tells the name and cash price of each article, and (in last column but one), gives the number of names sent in at the regular price of \$1.60 a year that will secure any premium article. (The last column gives the number of names at the lowest club price for 20 or more names, that is \$1.10 each, but only a part of the premiums come under this head. Some persons quickly raise large clubs by taking all the names at \$1.10 each, and themselves pay the difference, 50 cents each, and even thus get the premium articles very cheaply.)... (a) All subscribers sent by one person count, though from several different Post-offices. But... (b) Tell us with each name or list of names sent, that it is for a premium.... (c) Send the names as fast as obtained, that the subscribers may begin to receive the paper at once. Any one can have any time desired, up to next July, to complete any list, but every premium desired will be sent as soon as earned and ordered.... (d) Send the exact money with each list of names, so that there may be no confusion of money accounts.... (e) Old and new subscribers all count in premium clubs, but a portion at least should be new names; it is partly to get these that we offer premiums to canvassers.... (f) One or two Specimen Numbers, etc., will be supplied free, as needed by canvassers, (when 3 cents per copy is furnished to pre-pay postage), but they are expensive, and should be used carefully and economically, and where they will tell. Other specimen numbers will be sent, post-paid, to canvassers only, for 10 cents each. The price to others is 15 cents.... (g) Remit money in Checks on New York Banks or Bankers, payable to order of Orange Judd Company, or send Post-office Money Orders. If neither of these is obtainable, Register Money Letters, affixing stamps both for the postage and registry; put in the money and seal the letter in the presence of the Post-master, and take his receipt for it. Money sent in any of the above ways is at our risk; otherwise it is not.

Premium Articles for Sale.
It often happens that persons, who have not time to secure these valuable and useful premium articles by raising clubs of subscribers, are desirous of purchasing one or more of them, and wish us to procure or select them. For the accommodation of such, we will supply and send most of these premiums for cash, at the prices in the Descriptive List, and prepaid or otherwise, as stated.

Table of Premiums

For Subscribers to American Agriculturist.

(In the following table is given the price of each article, and the number of subscribers required to get it free, at the regular rates of \$1.60 a year, and also (with a part of the premiums), at the club rates of \$1.10 a year, postage included, which is prepaid in all cases by the Publishers.)

TABLE of Premiums and Terms				Price of Premiums	Number of Subscribers required at or above
For Volume 37—(1878).					
Open to All—No Competition.					
No.	Names of Premium Articles.				
1	Tea Set (Middletown Plate Co.)			\$50 00	66
2	Ice Pitcher (do. do. do.)			\$13 00	20
3	Cake Basket (do. do. do.)			\$7 50	16
4	Cake Basket (do. do. do.)			\$10 00	18
5	Casters (do. do. do.)			\$5 25	13
6	Casters (do. do. do.)			\$7 50	16
7	Casters (do. do. do.)			\$10 50	19
8	Butter Cooler (do. do. do.)			\$6 50	15
9	Pickle Jar and Fork (do.)			\$5 00	12
10	Syrup Cup with plate (do.)			\$6 25	15
11	Child's Cup (do.)			\$3 50	8
12	Twelve Teaspoons (Meriden Cutlery Co.)			\$7 25	16
13	One Dozen Tablespoons (do. do.)			\$14 50	22
14	One Dozen Table Forks (do. do.)			\$14 50	22
15	Ladies' Folding Pocket Scissors (do.)			\$1 50	4
16	Child's Knife, Fork & Spoon (do.)			\$3 00	9
17	French Cook's Knife, Fork, & Steel (do.)			\$3 75	9
18	Case of Scissors (U.S. Steel Shear Co.)			\$4 00	10
19	Portable Writing Desk, (C. W. F. Dore)			\$1 75	4
20	Walnut Work Box (do.)			\$1 25	4
21	Buck-Saw for Boys (do.)			\$1 50	2
22	Little Girl's Wash Set, (do.)			\$1 00	3
23	Sled, (do.)			\$2 00	5
24	Spring Horse, (do.)			\$11 00	18
25	Boy's Wagon (C. W. F. Dore)			\$5 00	12

27	Boy's Larger Tool Chest (do.)			\$2 50	7
28	Boy's Larger Tool Chest (do.)			\$5 00	12
29	Pat. Magic Belthead Pencil (Ludden & Taylor)			\$1 50	4
30	Ladies' Magic Charm Pencil (do. do.)			\$2 00	5
31	Gents' Magic Charm Pencil (do. do.)			\$2 75	7
32	Gold Pen, Telescopic Case (do. do.)			\$3 50	7
33	Gold Pen and Pencil, Elegant (do. do.)			\$5 50	13
34	Knives and Forks (Patterson Bros.)			\$14 75	22
35	Knives and Forks (do. do.)			\$18 50	28
36	Carver and Fork (do. do.)			\$3 75	9
37	Pocket Knife (Meriden Cutlery Co.)			\$1 50	4
38	Pocket Knife (do. do.)			\$2 00	5
39	Pocket Knife (do. do.)			\$2 75	7
40	Ladies' Pocket Knife (do. do.)			\$2 00	5
41	Mullum in Parro Knife (do. do.)			\$3 50	8
42	Crandall's "John Gilpin" (do.)			\$1 00	3
43	Crandall's "District School" (do.)			\$1 00	3
44	Crandall's Masquerade Blocks (do.)			\$1 00	3
45	Crandall's "Acrobats" (do.)			\$1 00	3
46	Crandall's Building Blocks (do.)			\$1 50	4
47	Crandall's "Menagerie" (do.)			\$2 00	5
48	Pair of Skates (Patterson Bros.)			\$3 50	8
49	Boudoir Clock (S. B. Jerome & Co.)			\$3 50	8
50	Wire Bed Mattress (H. Buckingham)			\$12 00	19
51	Houchin's Patent Pocket Cook Store			\$1 35	4
52	Household Press, (W. A. Boardman)			\$2 00	5
53	Aquapull, (Force Pump), (W. & B. Douglas, Middletown, Conn.)			\$9 00	17
54	Self-adjusting Gold-plate Watch Key, (J. S. Birch)			\$1 00	3
55	Pocket Tool Holder (Miller's Falls Co.)			\$1 00	3
56	Planer, Splendid 7-foot, (Steinway & Son's)			\$650 00	625
57	W. S. Blunt's "Universal Force Pump"			\$12 00	19
58	Silver Watch (American Watch Co.)			\$30 00	44
59	Bracket Saw (Miller's Falls Manf' Co.)			\$1 25	4
60	Payson's Indelible Ink—Pen, etc.			75	3
61	Excelsior Pocket Microscope (Bausch & Lomb Optical Co.)			\$2 75	7
62	Abbott Pocket Microscope (L. G. Abbott)			\$1 50	4
63	Cahoon's Broadcast Seed-sower (do.)			\$5 00	12
64	Moore's Floral Set (Moore, May & Co.)			\$1 00	3
65	Garden Seeds & Flower Bulbs (select'n)			\$2 00	5
66	Planet Jr. Combined Drill & Hoe (S. L. Allen & Co.)			\$12 00	19
67	Breech-loading Pocket Rifle (Stevens)			\$16 00	24
68	Double Barreled Breech-loading Gun (do.)			\$50 00	66
69	Shot Gun (E. Remington & Sons)			\$6 00	14
70	Shot Gun, breech-loader, (do. do.)			\$35 00	36
71	Creedmore Long Range Rifle No. 1 (do.)			\$10 00	19
72	Creedmore Long Range Rifle No. 2 (do.)			\$15 00	24
73	Creedmore Long Range Rifle No. 3 (do.)			\$20 00	32
74	Hunting & Target Rifle (Remington)			\$22 00	34
75	Vest Pocket Pistol (Remington)			\$3 75	9
76	Revolver (Remington)			\$9 00	17
77	Turn-table Apple Parer (Goodell Co.)			\$1 00	3
78	Climax Apple Corer & Slicer (do.)			\$1 00	3
79	Family Cherry Stoner (do.)			\$1 00	3
80	Bay State Apple Parer & Slicer (do.)			\$1 50	4
81	"Saratoga" Potato Peeler & Slicer (do.)			\$1 00	3
82	Sewing Machine (Remington)			\$50 00	66
83	Family Scales (Fairbanks & Co.)			\$14 00	21
84	Clothes Wringer (Best—Universal)			\$8 00	16
85	Worcester's Great Illustrated Dictionary			\$10 00	18
86	Any Back Volume Agriculturist			\$1 75	20
87	Any Two Back Volumes do.			\$3 50	35
88	Any Three do. do.			\$5 25	45
89	Any Four do. do.			\$7 00	55
90	Any Five do. do.			\$8 75	65
91	(Each ad'l Vol. at same rate)				
92	Twenty-one Vols. XVI to XXXVI			\$36 75	53
93	Any Back Vol. Agriculturist			\$2 50	25
94	Any Two Back Volumes do.			\$4 00	40
95	Any Three do. do.			\$6 00	60
96	Any Four do. do.			\$8 00	80
97	Any Five do. do.			\$10 00	100
98	(Each ad'l volume at same rate)				
99	A \$10 Library (your choice)			\$10 00	18
100	A \$15 Library do.			\$15 00	24
101	A \$20 Library do.			\$20 00	31
102	A \$25 Library do.			\$25 00	38
103	A Choice of Good Books. (See Description, p. 408.)				

Every Premium article is new and of the very best manufacture. No charge is made for packing or boxing any article in our Premium List. The Premiums, Nos. 15, 18, 29 to 33, 37 to 41, 49, 51, 54, 55, 59 to 62, 65, 75, 76, 86 to 102, inclusive, will each be delivered FREE of all charges, by mail or express (at the Post-office or express office nearest the recipient) to any place in the United States or Territories.—The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance desired. Illustrated and Descriptive List sent free to applicants.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from p. 209.

Gapes in Chickens.—"A Subscriber," Newport, R. I. Gapes is caused by the presence of small worms in the wind-pipe. Young herbivorous animals of all kinds are very subject to these parasites, the eggs of which are supposed to be dropped in the excrements of the older animals, and swallowed by the young ones. Prevention is the best remedy. This consists, in regard to poultry, in removing all the droppings from the houses, keeping the soil of the yards fresh by digging over the surface, or providing new locations for them every season. Some camphor dissolved in the drinking water is said to be a remedy, but as we have always avoided the disease by precaution in our yards, we have no experience as to alleged cures.

To Estimate the Amount of Cord Wood in an Acre.—"E. L.," St. Louis. To estimate the quantity of cord wood on an acre of wood land, requires experience. A person who has been engaged in clearing land and cutting wood, could give a very close estimate at a glance, but other persons would make the wildest guesses. An inexperienced person may proceed as follows: measure out 4 square rods of ground; that is, 33 feet each way, and count the trees, averaging the cubic contents as near as possible of the trunks, and adding one-fourth of this for the limbs. Then, as 128 cubic feet make a cord, and the plot is one fourth of an acre, the result is easily reached. Fairly good timber land should yield a cord to every 4 square rods. A tree two feet in diameter and 30 feet high to the limbs, will make a cord of wood, if it is growing in close timbers, and the limbs are not heavy. If the limbs are large and spreading, such a tree will make 1½ to 1¾ cords. A tree one foot in diameter will make only a fourth as much as one twice the diameter. In estimating, it is necessary to remember this fact.

Oil-Meal-Corn-Mill.—"W. L. C.," Sullivan Co., Pa. Linseed, cotton-seed, and oil-cake, are very valuable feeding stuffs. They are worth more than corn, and should be fed in small quantities. We are using the Big Giant corn-mill, and find it a good one. The Orange Judd Company keep no seeds for sale.

The Dodge Hay Press.—By an oversight, the address of the manufacturers of the Dodge Hay Press was omitted in the article describing this press in the *American Agriculturist* for Oct., 1877. The manufacturers are the Mohawk and Hudson Manufacturing Co., Waterford, N. Y.

Directions for Castrating and Spaying.—"J. D. B.," Jackson, Mich. These operations are described in Dr. Dadd's *American Cattle Doctor*.

The Value of Corn-Fodder.—"R. S. H.," Lennoxville, Canada, writes: "I have tried most all kinds of corn as a dry food for stock in winter, from the Dwarf Sweet to Evergreen Mammoth, and find no other gives so good returns as the early Sugar corn. It is very sweet, will grow in good ground six feet high, and if sowed thick in drills, will give from five to six tons of excellent fodder per acre. It should be sowed about the first of June in drills, two and a half feet apart in rich ground, and if the season is any way favorable, can be cut from the first to the middle of August. It should be bound in small bundles and set up in shocks, to dry, and it will become so well cured before wet weather sets in, that it can be packed away as well as hay, or straw, without being damaged by moulding. The seed should be sowed thick, not less than two bushels of good seed per acre. Horses, cattle, and sheep, are very fond of it, and with a small quantity of hay thrive well, and milch-cows do much better than when fed upon hay alone. It requires the manure in the drill, so that the corn will have a quick growth and it will be very tender.

Soot on the Garden.—"H. M. B.," Waterbury, Conn. Yes, soot from chimneys is of value in the garden, and is, so far as known, excellent for all crops, but too scarce and valuable to be wasted upon the coarser kinds. Soot is the condensed matters which escape in the combustion of wood and bituminous coal. The constituents of the wood and coal form various new compounds which, coming in contact with the cool chimney, condense and harden there. Our common hard

coal (anthracite), forms no soot proper. Soot consists largely of charcoal, various salts, especially those of ammonia, and peculiar substances related to creosote. We can not put our hand on a good analysis showing the difference between soot from wood and from soft coal, and a recent work says such are much needed. There is a general impression that the soot of bituminous coal is the richer in ammonia salts. In Europe, where it may often be procured in large quantities, it is highly valued for all crops to which ammonia is beneficial, at the rate of 15 to 30 bushels per acre, on wheat and grass crops. In the garden its value as a fertilizer is scarcely greater than that of an insect destroyer; its creosotic matters being very fatal to most insects. For the garden it is very economically used as a liquid, 6 or 8 quarts to a hoghead of water. This remarkably stimulates plants that need it, and clears most of them from insects. Any gardener who has a good supply is fortunate.

Yellow Strawberry.—"J. S. G.," Dayton, O. There are several so-called "white" strawberries that are more yellowish or cream-colored than white. "Lennig's White" is cream-colored, with a fine blush, one of the handsomest as well as best of berries—when you get it. Then there are three or four of the Alpine class with white fruit, including the Monthly and Bush Alpines. A poor variety, called the "White Carolina," was formerly cultivated, and two, at least, of the Chilean strawberries would be classed as white; they have enormous fruit, but would not stand our climate. If you saw them "a great while ago," probably it was one of the Alpines, which are still cultivated by those who like them.

Alfalfa in New Brunswick.—"F. W. H.," St. Johns, N. B. Alfalfa is a plant that thrives best in dry climates. It was brought from Chili, a dry South American country, to California, where the climate is very dry. There it has thriven to a remarkable degree. But wherever there is moisture enough to produce good clover, alfalfa has not succeeded. It could not be grown in New Brunswick so profitably as clover, and it is a question if it would grow at all.

To Kill Wild Rose Bushes.—"G. F. C.," St. Joseph, Mich. To destroy wild rose bushes it is necessary to kill the roots, or they will throw up suckers and perpetuate the growth. This is a difficult plant to get rid of in most meadows. The best method known to us is to mow the bushes when the roses are in bloom, or in July, and if sprouts appear later, to cut them down before they ripen their wood. Later growth will be tender, and not survive winter. Next year they will be weak and sickly, and this treatment continued will destroy them.

Very Strange.—"W. W. Rubottom, of Spadra, has a rose tree with green roses upon it. * * * This curiosity is said to be the result of budding the white rose upon the Weeping Willow."... A green rose is not so strange, as we had one some 20 years ago, and have had them several times since. The manner in which "it is said to be" produced is strange, and would be stranger still were it true; but the strangest of all is that such false teaching should be found in the "Southern California Agriculturist," a journal generally so sensible in its teachings and so full of excellent promise.

Drawing Water with a Siphon.—"G. H.," Stark Co., Ohio. Water can not be drawn with a siphon over a height of more than 25 to 28 feet. If the pipe is very smooth inside, and the flow of water is larger than one inch, a rise of 28 feet may be overcome; otherwise the friction and the adhesion of the water to the surface of the pipe, will prevent the flow from rising more than 24 or 25 feet.

Feeding Cattle for Profit.—A statement, made by an Irish farmer, relative to the feeding of calves from birth to ripeness for the butcher, with the method of feeding, and the cost, and the profit, is not without interest to us, when we consider the importance of the profitable feeding of animals, and the value of the manure to our rapidly changing system of agriculture. The calves cost \$10 when two weeks old; that is, the dairy was credited, and the stock account was charged with that sum, when the feeding of the calf was begun. Each calf received 4 quarts of skim milk per day, for 108 days, and for this period a daily average of 10 ounces of a mixture of linseed and cotton seed cake boiled with the milk, with four pounds of roots and green feed, and one pound of hay. After four months old, the daily ration was a pound and 4 ounces of a compound made of one part bran, one malt dust, two rape-cake, two linseed-cake, and four cotton seed cake, thoroughly broken and mixed together. Each month the ration was increased about five ounces per day. 7½ lbs. of roots or green clover, and 2 pounds of chaffed straw were also given. The food cost about 4½ cents a pound, and the expense of feeding could thus be closely calculated. The following

table gives the result of feeding nine head of well bred animals, steers and heifers, from 18 to 25 months old.

Age, Months.	Dressed Weight.	Value.	Value of Manure.	Cost.	Profit.	Profit, per cent.
18	606	\$113.60	\$22.25	\$110.00	\$25.85	30
—	557	104.43	20.41	103.52	21.32	27
—	492	92.75	18.04	90.25	20.54	29
19	631	118.30	24.25	114.70	27.85	29
21	732	137.25	29.17	135.75	30.67	24
22	660	123.75	27.50	130.50	20.75	18
23	724	135.75	32.30	148.43	19.62	15
24	748	140.43	36.62	163.51	16.54	9½
25	748	140.25	38.25	169.75	8.75	6

The figures show a fact which is neither new nor surprising, viz., that the longer an animal is fed after it is mature, the profit decreases; or to use a well understood expression, after it has reached a salable age it begins "to eat its head off." This exemplifies also the fact that without keeping an accurate account of cost, etc., we can not hope to know the precise point where profit ends and loss begins. Generally the point is about the age of 20 months; that is, with early maturing breeds.

Tumors on the Legs.—"C. S.," Leominster, Mass. In scrofulous animals hunches, nodules, or tumors, frequently form upon the limbs. When these are upon a joint, it is sometimes dangerous to meddle with them, because in such conditioned animals wounds do not often heal readily, and an open joint may ensue, to the final destruction of the animal. So long as there is no lameness, it would be well to do nothing more than to apply a mixture of 7 parts of Glycerine and 1 part of Iodide of Potassium, which may help to the absorption of the tumor.

How to Burn Marl into Lime.—"J. S. P.," Bonneau's Depot, S. C. Marl can be burned into lime more or less impure according to the nature of the deposit, by putting it into heaps with brush-wood in alternate layers upon a foundation of logs, and setting the logs on fire. When the heap is thoroughly ignited, it should be covered with fine green brush and earth to confine the heat. In three days the operation will be complete. Shell marl, which is an impure carbonate of lime, and not the "green sand marl," if thus treated, will be made into a valuable fertilizer.

Soft or Hard Water for Cattle.—"C. H.," Ontario, Canada. Limestone water is probably not injurious for cattle and horses. In limestone districts we have the best grass, the best grain, and the best stock. The choicest localities, such as the blue grass region in Kentucky, Western New York, the Shenandoah Valley in Virginia, and the Missouri Valley in Ohio, are all in a limestone country with hard water.

How Many Calves can a Cow Raise.—"Q. A. B.," Meigs Co., Ohio. A good cow may be expected to milk during eight months of the year sufficiently to support a calf. If she is kept for raising calves, and the calves are weaned when 2 months old, she can supply four calves. When a calf is 2 months old it may be supported upon other food than milk, so that by managing well, one good cow can be made to raise 4 calves, if not more. A good milker, when fresh, will yield more than enough to feed one calf, and at least two calves can be fed from her milk for two or three months. If calves are designed for beef cattle, it is advisable to procure a good Shorthorn or a Hereford bull to sire them.

Corn Harvester.—"M. C. C.," Whiteside Co., Ill. A harvester that would cut corn and drop it in bundles, would certainly be a valuable machine, and if sold at a reasonable price, would be generally used. It is one of the improvements that farmers are anxiously waiting for. There are several machines made for this purpose, but none as yet that are satisfactory.

"A Hollow Tail."—"J. B.," Butler Co., Pa. In every cow's tail there is a portion where the bone is wanting, and the part is soft. This is natural, and not a state of disease. "Hollow Tail," and "Wolf in the Tail," are terms that have no significance, beyond the mere fact that something is wrong with the cow. It is not in the tail at any rate.

The German Farmer's System.—The mission of the true American seems to be to chase the setting sun. Ever on the march towards the west; or ever looking with longing eyes towards that wished for but unattainable locality which may be called his final resting place—because there is no beyond to it for him, and he can not go back—he is engaged chiefly in getting what he can from his land now, without thinking of the future. His successor, when he finally makes a sale, and westward flies, is a German farmer, in the majority of

cases. But the German comes to stay; and having no thought of "the West," he sets about cultivating his farm in a methodical manner. He works without stint, and he saves without grudging; being industrious and economical, he succeeds and makes money rapidly. His children are as industrious and as careful as he, and his frau takes a hand with the hoe and does not regard the latest fashion in her dress. By and by the boys and girls marry, and the son is presented with a farm, the daughter with a dowry to start with, and the youngest boy sticks to the farm. Where such people live, thrift abounds.

Value of Gas Lime.—"Ottawa," Canada. Gas lime, when fresh, contains poisonous matter injurious to vegetation. But when it has been exposed to the air for some months, these bad qualities are lost, and the lime becomes mainly a mild carbonate. It may then be used upon clay or peaty soils, or meadows, at the rate of 50 to 100 bushels per acre, with benefit.

Treatment of Hoove.—"J. F. W.," Lancaster Co., Pa. When a cow is "blown," or suffering from "hoove," relief is often gained by giving one ounce of carbonate of ammonia dissolved in water, and a purgative soon after. If the cow has eaten too much dry feed, it is not well to give much water until the purgative has worked off. If she is "blown" by green feed, such as clover, the quickest remedy is to use the trochar and open the paunch, leaving the tube in the opening until the gas is no longer emitted.

Teasels as Handles.—Not the prickly remains of the flower heads, used to "tease and tear" a nap upon woollen cloths—lively handles these would make—but the stems upon which these heads grow. These have been imported into England from the Continent in considerable quantities, and are likely to appear as one of the novelties of the season, as handles to ladies' sunshades and parasols. These teasel-stems are variously twisted, bent, and furrowed, and made more grotesque by the "fasciation" or soldering together of the branches, as we often see in asparagus and cockscombs.

Prices of Ordinary Shorthorns.—We learn that sales of young pure bred Shorthorn bulls and calves have been effected to a large extent in Kentucky at about \$100 each; at this rate business is very brisk. 13 young animals were purchased by one buyer from Texas at an average of \$75 each. At such prices a large demand from farmers and breeders may be looked for, and if some breeders would confine their efforts to the production of milking strains, a very great demand would arise from dairymen.

Periodic Ophthalmia in a Horse.—"B. F. A.," Macon Co., Mo. In periodic ophthalmia the eyes become inflamed and covered with a film; this disappears for a time, and again appears, perhaps several times in succession. The final result, however, is almost certain blindness. The only treatment is palliative; give a dose of cooling medicine, as one pound of salts; keep the horse in a clean stable; bathe the eyes in a solution of 4 grains of sulphate of zinc, in one ounce of water, and inject a little into the eyes.

Oil Paintings Distributed.—A large number of persons have sent as circulars, tickets, etc., of "A Grand Testimonial Gift Distribution of Oil Paintings." It seems that there has been a "drawing" of some kind, and those who have "drawn" pictures can have them by paying \$2.10, to cover "expenses," and the express charges. We have received numerous requests to show this up as a "humbug." So far as the distribution is a game of chance, so far we hold it to be wrong. Of course the projectors of the scheme have an object in view. They are not afflicted with such a fit of generosity as will induce them to send paintings all over the country at one-tenth or one-twentieth of their value, unless they expect to gain something by it in the end. Now, while we utterly discountenance every game of chance, no matter by what name it may be called, we have no right—and in the question of humbogs we have to consider that both parties—the accusers and the accused, have rights—to set this matter down as a "humbug" unless we know it to be such. It all rests upon the question: is the painting sent—and recollect that no one is obliged to send for it—worth the cost of the \$2.10 for expenses and the express charges. Now notions greatly differ. Let us suppose that all told, the cost of the painting is \$5 to the one who receives it. If asked if an oil painting was worth \$5, we really could not say. We could readily say that if an oil painting was, as such things sold at auction in New York, or other large city, and this is an excellent test of real value—only worth five dollars, or five times five dollars, we should not like to be obliged to possess it. But ideas, or notions, differ—we will not call them *fastes*, for they have not reached to that. There may be people—no doubt there are—to whom an "oil

painting," which could be produced for \$5, at a profit, would be quite satisfactory. We can not write the thing down as a humbug, unless we know that the pictures are worth less than they cost to those who receive them. The only evidence we have as to the kind of paintings sent out, is from a lady in New Jersey, who writes:—"The painting has come, and it is one of the vilest, cheapest daubs imaginable, not worth the canvas it is on, and instead of adorning, as they say, 'the walls of the most sumptuous homes,' I would not put it in my kitchen, and would not give 25 cents for it." But as the thing is a game of chance—a "Gift Distribution,"—the next painting may be worth 37½c. or 50c., and so up along. We can only say to those who do not like these offers, it is the easiest thing in the world to let them severely alone.

How to Rot Straw.—"J. T. G.," Sulphur Hill, Ind. Straw alone is not easily decomposed. This is seen in the case of straw used for thatched roofs, some of which are a hundred years old or more, and are yet sound. Still they have been exposed to heat and cold and wet for all these years. Straw can only be rotted quickly by mixing some actively fermentable matter with it. But straw may be used on Western farms to good purpose, by spreading it upon the ground and plowing it in. Thus all the benefit that could be derived in any way from the straw, will be gained by the soil, because in whatever manner we use the straw we do not really add anything to it. Much good may also be derived by spreading straw over winter grain, as a mulch and a protection against sudden changes of the weather in winter.

Why do Hogs Eat Coal?—"H.," Reno Co., Kansas. Swine are intended by nature to get a portion of their subsistence from roots, and to dig these roots from the soil by means of their snouts, which are well adapted to this. In eating roots so procured, a large quantity of soil, or mineral matter, is swallowed, and it seems to be intended by nature that this should be done, as, when prevented from pursuing their natural bent, they evince a strong appetite for such things as coal, earthy substances, or even decayed wood. It is always healthful for hogs that are closely penned, to be supplied with sods, soft coal, or charcoal, moderately, but when they have been deprived of these for some time, caution should be observed lest they consume them to excess.

A Question of Manuring.—"R. C. M.," Olney, Ill. It is not always that the trouble and cost of composting manure will be repaid by the benefit gained. Sometimes it is cheaper in the end to spread manure as it is hauled through the winter on to the ground. Where land is flat the danger of washing is very little or nothing, except under unusual circumstances. As to this, judgment should be exercised. Unless it is very clear that a gain is to be made by laborious composting, that course is not advisable; it is better to cart the manure directly on to the land, and spread it at once; not leaving it in piles more than a day or two at the utmost. When manure can be had plentifully for the hauling, it will not pay to compost it. That is only a device to increase the bulk of the manure when it is scarce and costly.

How to Keep a Hydraulic Ram at Work.—"J. A. G.," Lewisburg, Pa., writes that if a small air-hole is made in the feed pipe of a water ram, about two inches in front of the ram, there will be no stoppage on account of want of air in the air-chamber. He has had a ram at work for 30 years without ever a stop from this cause, except when back-water covered the hole. If the hole is too large, it may be made smaller by tapping around it with a riveting hammer.

Cheese Factory in New Jersey.—"F. P.," Woodstown, N. J. We do not remember of any cheese factory in the State of New Jersey, excepting those in which "foreign" cheese is made, or rather imitations of a French and other European cheeses. Doubtless there are openings for such factories in many parts of the State. The capital required for a small factory is not heavy. The building need not be expensive; the machinery can be furnished complete by Whitman & Burrell, of Little Falls, N. Y., who would give estimates on application. See articles in February number.

To Repair an Old Chain-Pump.—"S. W.," Mineola, L. I., gives the following plan for mending an old chain-pump that will not raise the water. First take a stout cord; make the chain fast, so that it cannot drop down the cistern or well, then unhook one of the bucket-links, take the heel of an old India-rubber boot, or some rubber packing; cut a hole through the rubber, press one eye of the bucket-link through sufficiently far to admit of linking again, and then with a sharp knife pare the rubber down sufficiently small, so that it will exactly fit the trough; the round, penny-shape bucket will be a sufficient guide in cutting the rubber-bucket perfectly round. Then re-link the bucket upon

the chain, and repeat this on every fourth bucket the entire length of the chain; it is unnecessary to put the rubber-buckets closer than every fourth one. Be careful that when putting the rubber-buckets back on the chain, that the old metal bucket shall be under the rubber one when entering the trough, so that it will be supported and held firm by pressure against the trough. Do this carefully, and your old pump is good for several years longer, and it will throw water faster than when new.

Economy in Cutting Feed.—"A. Q. McG.," Estes Park, Colorado. The economy in cutting feed consists in the prevention of the waste which occurs with long feed, and also in the less consumption. It is very certain that a less weight of long fodder, cut, moistened, and mixed with ground grain, will keep an animal in equally good condition as a larger quantity of uncut fodder with ground grain. This effect occurs in two ways; the animal exercises less muscular exertion in masticating the prepared food, and the food is more perfectly digested. We have found the saving to be from a fourth to a half with some animals that are of unusually wasteful habits, or of inferior digestive powers.

Value of Pond Sediment.—"H. T.," Milltown, N. B. The soil left by the draining of ponds is generally very valuable for meadow land. A pond that is filled with mud to within 6 inches of the surface, may doubtless be drained by cutting an outlet to carry off the water. The mud will settle considerably, and the drain may need to be 5 to 6 feet deep. As soon as the surface is dry, it should be sown with grass seed, lest bog grasses spring up and produce a growth of tussocks, which would spoil the surface. Open ditches should be cut through the ground as soon as the surface is solid enough to work upon. The reclamation of such land will require probably two years, if not more.

Spaying Sows.—"J. W. P.," Wells Co., Ind. There is no certain way of preventing sows from breeding except by spaying. There are different other methods proposed, but they are all shams and humbugs.

Pennsylvania Corn.—"C. C. E.," Waynesburg, Ohio. A very large and prolific variety of yellow corn is grown in Southern Pa. We have grown it, having 32 rows, and shelling nearly a quart to each ear. But it requires very rich soil and a climate equally warm as that where it originated.

Concrete for Cellar Walls.—"T. E. W.," Clinton Co., Ohio. Concrete makes a very strong cellar wall. It is stronger and better in every way when made with hydraulic lime (or cement), than with common lime, although a good concrete may be made with common lime. We have built walls of each kind of concrete, and much prefer the hydraulic cement.

Artesian Wells.—"J. L. B.," Greenland, W. Va. Water can not always be made to overflow from a well, however deep it may be. There must be an underground stream tapped, which has its source above the level of the mouth of the well, and the stream must be confined by an impervious bed of clay or rock. Unless these conditions exist, no flowing well can be had.

Plowing Under Green Crops.—"C. S.," Syracuse, N. Y. It is a great mistake to suppose that land too poor to grow anything, can be restored by growing and plowing under green crops. Green manuring is useful to keep good land in good condition without other manure. But to raise the condition of poor land in this way, would be to get something out of nothing. The easiest manner of restoring poor soil, is to use some artificial fertilizer to grow clover, and then plow under the clover.

Sulphate of Copper as a Tonic for Pigs.—"R. L. C.," Sulphate of copper, properly used, is a valuable tonic for animals. The proper quantity is from half a dram to two drams for a horse, ox, or cow; 10 grains to a sheep, and 15 grains for a pig. It is poisonous when given in large quantities, as are almost all medicinal drugs. Sulphate of iron (copperas) is less active than the sulphate of copper (blue vitriol), and is used in doses four times as large. It requires a knowledge of the case to distinguish the need for the one or the other of these drugs.

To Split Knotty Logs.—"B.," Cheshire Co., N. H., writes: Take a six or seven-quarter auger for large, tough, knotty logs that are to be split. Bore into the log you wish to open, for one-third or one-fourth its diameter, put in a good charge of powder. Take a piece of wood six or eight inches long, suitable to make a spile or plug—pine is the easiest to work, and the best—run a ¾ hit through the tap—that is, to be fitted to drive tight and firmly to the charge—then prime and set a match that will give time to get out of the way.

Nuts and Nubbins.

"Sealskin sacks are worn longer." Same way with all the rest of our clothes.

When a man has no bills against him he feels as though he belonged to the nobility.

"How's your husband this evening, Mrs. Quaggs?"—"No improvement, doctor, one way or the other."

A little boy went to his father crying, and told him that he had kicked a bee that had a splinter in its tail.

Among the items in a plumber's bill are: to searching gas leakage, fifty cents; to having found it, one dollar.

"I'ze right," shouted a military officer to his company. "Well," grunted a green private, "nobody said you wasn't right."

A young housekeeper, when her attention was called to a very dusty chair, remarked: "Nobody has sat down on that to-day."

A Rochester man hung a sign in front of his place of business, which reads: "Twenty-five loafers wanted to stand here." They don't stand there.

"Nice little girl: 'Oh, do let me see you drink.'"—Captain Grogson: "Why, my dear?"—"Nice little girl: 'Because ma says you drink like a fish.'"

Some Indians use scalping knives of tortoise shell, probably on account of the old fable in which the tortoise was alleged to have got away with the hare.

"A polite man," said the Duc de Morny, "is one who listens with interest to things he knows all about when they are told by a person who knows nothing about them."

A mother seeing her little four-year-old nearly asleep in her chair, asked if she had not better go to bed.—"Oh, no, mamma; I only shut my eyes to keep the dust out."

"How does the new cow answer?" asked one man of another who had lately purchased a cow.—"I really can't say," he replied, "for I've never asked her any questions."

"My dear," asked Mrs. J. of her husband, on coming home from church the other day, "what was the sweetest thing you saw in bonnets?"—"The ladies faces," was the bland reply.

Physician.—"Your pulse is still very high, my friend! Did you get the leeches all right day before yesterday?"—**Patient.**—Yes, sir, I got 'em right enough; but mightn't I have 'em bled next time?"

The following conversation took place recently in an hotel: "Waiter."—"Yes, sir."—"What's this?"—"It's bean soup."—"No matter what it has been; the question is, what is it now?"

A Boston paper says: "A butterfly was caught at the South End yesterday."—It may be safe enough to catch a butterfly at the South End, but when you go to grab a wasp you want to catch it at the northeasterly end, shifting westerly toward the head.

"Ma," said a thoughtful hoy, "I don't think Solomon was so rich as they say he was."—"Why, my dear, what could have put that into your head?"—"Why, the Bible says he slept with his fathers; and I think if he had been so rich, he would have had a bed of his own."

When you see a lady on the street stop and suddenly kick and reach backward and downward, don't be alarmed; it is not a brickbat she is after. As soon as she shakes out the old oyster cans entangled in her trail, that same sweet smile will return; and everywhere the street contractor hails the woman with a trail as a blessing.

A gentleman who happens to own a paddock, and who had tried every effort and threat in vain to prevent tramps from making a short cut through it, was eventually persuaded to stick up the following notice: "Beggars, Beware! Scolopendriums and Polypodius planted here." The effect was marvellous, and the annoyance ceased.

The young ladies of Vassar College feel quite at home in studying chemistry. They are at once on friendly terms with Sal Ammoniac, Sal Soda, Sal Prunelle, Mag Nesium, Moll Yhdenum, Ann Timony, Cad Mium, Ruth Enium, Pete Roleum, Al Umium, Doll O'Mite, Bessi Mer's Process, Mary Otte's Law, and Ann Alysia.

A young man, on becoming affianced, was desirous of presenting his intended with a ring appropriately inscribed; but, being at a loss what to have engraved upon it, he asked his father's advice. "Well," said the old gentleman, "put on, 'When this you see, remember me.'" The young lady was surprised, upon receipt of the ring a few days after, to read this inscription: "When this you see, remember father."

Mr. Basingbal (city merchant)—"Most convenient! I can converse with Mrs. B. just as if I was in my own drawing-room. I'll tell her you are here." (Speaks through the telephone.) "Dawdles is here—just come from Paris—looking so well—desires to be," etc., etc. "Now you take it, and you'll hear her voice distinctly."—Dawdles—"Weally!"—(Dawdles takes it.)—The voice—"For goodness sake, dear, don't bring that insufferable noodle home to dinner!"

WILLIAM CROZIER has much pleasure in calling the attention of Cow-keepers, Farmers, and Dairymen to the **NEW SELF-MILKING APPARATUS**. This Apparatus or Cow Milker, has been tested by a large number of practical Agriculturists, Dairymen, &c.; and, without exception, merited high encomiums and commendations, for its adaptability and wonderful rapidity in the Milking of Cows. It is considered one of the most invaluable and useful Machines yet invented.

Amongst its many advantages are—

1st—It is **SELF-ACTING**, easy of application; and can be used by any person, however ignorant of Milking.

2nd—It will Milk any Cow in **FOUR Minutes** effectually, and its use is more agreeable to the Cow than Hand-Milking.

3rd—It is a great boon in the case of Sore or Corded Teats.

4th—Its Usefulness, Simplicity, Saving of Time, Cleanliness, Durability, and Cheapness, prove it to be a most important and necessary adjunct to a Dairy, and it has only to become better known to be universally used.

Send free on receipt of Post Office order for \$5.

Printed Instructions accompany each Machine.

All infringements will be vigorously prosecuted.

MILK TUBES.

COW-KEEPERS should not be without one of these, as they are invaluable for sore or Corded Teats.

PRICE \$1.00 each.

WM. CROZIER, Northport, L. I., N. Y.

4 Grade Jersey Calves; A heifer 8 weeks old, white and dark fawn; Three Bulls 6 to 8 weeks old, dark fawn, all sired by Saunter, No. 2,147 Am. J. C. C. Dams, all extra cows. Prices—Heifer \$30; Bulls \$18; boxed on ears. Cash with order. Address **F. C. BIDDLE, Chadd's Ford, Pa.**

For Sale—3 Alderney Bulls, 2 thoroughbred and 1 ½ For pedigree, &c., address **JOHN A. GALLOWAY, New Dorp, Staten Island, N. Y.**

RIVERSIDE FARM—Jerseys, Berkshires, and Cots-wolds imported, bred, and for sale. Bronze Turkeys Pekin Ducks, and Light Brahmas. Send for catalogue. **C. P. MATTOCKS, Portland, Me.**

THOROUGHbred and GRADE

JERSEYS FOR SALE.

Thoroughbred **HEIFER CALVES**, weaned and unweaned.
do. **BULL CALVES**, do. do.
do. **YEARLING HEIFERS**, do. do.
do. **BULLS**, fit for service this spring.
do. **2-year-old BULLS**, do. do.
do. **HEIFERS**, in calf.
do. **HEIFERS and COWS**, 3 to 8 years old.

Grade Jersey Heifers and Cows of all ages, from two weeks to seven years old. I have nearly 100 head to select from. All my stock is bred expressly for their butter qualities, and no calves are raised from dams that do not yield 9 lbs. or more of splendid butter per week, when fresh. All orders requiring me to select for purchasers are solicited at once, as I shall fill them in turn as received, but I much prefer that purchasers examine for themselves. Terms reasonable. Apply at once to **THOMAS FITCH, New London, Conn.**

N. GUILBERT,

Evergreen Farm, Gwynedd, Pa.,

Importer and Breeder of Improved Blooded Live Stock, Horses, Cattle, Cotswood and Southdown Sheep, Chester, Berkshire and Yorkshire Pigs, Toulouse, Bremen, Hong Kong, White China and Wild Geese, Cayuga, Honen, Aylesbury, Pekin and Musk Ducks, Bronze, Blue, Buff and White Turkeys, Dorkings, Brahmas, Cochins, Guinea and all other Fowl, Deer, Swans, Peacocks, Pigeons, Eggs, &c., at low prices. Best Breeds of Dogs and Maltese Cats, Rabbits, Ferrets, Guinea Pigs, White Mice, &c. Song Birds of all kinds, and Shetland Ponies. Fine Milch Cows always on hand. Newfoundland Pups, Deer, and Swan wanted.

THOROUGHbred CATTLE, SHEEP,

PIGS and Poultry,

at such uniformly low prices as to prove a most profitable investment to every purchaser. Our present supply of young Berkshire, Chester White, Yorkshire, Poland China, and Essex Pigs, also of Cotswood, Southdown, and Leicester Lambs, is unexcelled. Correspondence solicited. Send for Illustrated Catalogue.

BENSON, MAULE & CO.,

223 Church St., Philadelphia.

WILLIAM CROZIER, BEACON HILL, Northport, L. I., N. Y., Importer and Breeder of Ayrshire and Jersey Cattle, Southdown Sheep, Berkshire Swine, English White Dorking Fowls, and Shepherd Dogs. Received a Medal and Diploma on stock at the Centennial Exhibition.

FRIENDS! If you are in any way interested in BEES OR HONEY,

We will with pleasure send you a sample copy of our **MONTHLY CLEANING IN BEE CULTURE**, with a descriptive price-list of the latest improvements in Hives, Honey Extractors, Artificial Comb, Section Honey Boxes, all books and journals, and everything pertaining to Bee Culture. *Nothing Patented.* Simply send your address on a postal card, written plainly, to **A. I. ROOT, Medina, Ohio.**

Poland China Swine, as bred by **FRANK PETTIT, Salem, New Jersey.** Large stock of first-class pigs for sale, now ready to ship; also yearling sows and six months gilts, due to farrow in one, two, and three months. All well formed, pure bred, and growthy, and are models of this unequalled breed of swine. Those wishing to buy, will please send for Price-list and Circular. Correspondence solicited.

JERSEY RED SWINE.

Have been bred in New Jersey 20 to 30 years, are now a distinct breed, and are relied on by the best Pork raisers as the most healthy, vigorous, and profitable breed; attaining heaviest weights, with least feed and care. Choice Pigs, 8 to 10 weeks old, now ready, boxed and shipped, guaranteed satisfactory and to arrive safely; one pig \$8—2 pigs, not akin, \$15—3 pigs \$30.

JOHN S. COLLINS, Moorestown, New Jersey.

"New Automatic"

SILENT SEWING MACHINE.

This machine stands **PRE-EMINENT** over all others in **QUALITY** and **MERIT**, and therefore commands a higher price. Persons seeking **THE BEST** sewing machine appreciate its **NEW AND VALUABLE FEATURES**, together with its **silence, lightness, swiftness, ease of working, simplicity and durability**. It is the **ONLY** sewing machine in the world with **NO TENSION** to manage, and is different from all other machines in its principles of operation, being **FAR IN ADVANCE** of any.

Descriptive Circulars on application.

WILLCOX & GIBBS S. M. CO.,
658 BROADWAY, NEW YORK.

Harvard University, Cambridge, Mass.

Summer Instruction in Science, for 1878,
For Teachers and other Adults.

Courses of Instruction will be given as follows:

I. General Chemistry and Qualitative Analysis,
by Mr. C. F. Mahery, Fee, \$25.
II. Quantitative Analysis and Chemical Technology,
by Mr. H. B. Hodges, Fee, \$25.
III. Determinative Mineralogy,
by Mr. W. H. Melville, Fee, \$25.

IV. Phenogamic Botany, by Prof. Geo. L. Goodale, Fee, \$25.
V. Geology, by Prof. N. S. Shaler, Fee, \$50.
Each Course will last six weeks. The first four courses will be given at Cambridge, and the fifth at a camp near Cumberland Gap, Kentucky. The fees are payable in advance, by mail or in person, to Allen Danforth, Bursar, Cambridge, Mass.

A circular which gives full information about these courses may be obtained by applying to JAMES M. HARRIS, Secretary, Cambridge, Mass., enclosing a stamped envelope.

THE LILLY BUTTER-WORKER

We guarantee it the best and cheapest Machine in the world. No hard labor. Mixes the salt thoroughly, and takes all the milk out, with five to ten minutes work. Circulars sent on receipt of stamp.

C. H. R. TRIEBELS, Successor to Henderson & Co., 316 Race St., Phila., Pa.

CHOICE BUTTER.

(From Massachusetts Agricultural College Farm.) "AMHERST, MASS., Feb. 9, 1878. VERMONT FARM MACHINE COMPANY: We are so well pleased with the Cooley Creamer that I feel bound to say a word in its favor. It takes us only twenty minutes to churn, and the extra yield of butter is wonderful. I have cheerfully recommended it to the Japanese government above all other systems. Yours very respectfully, A. A. SOUTHWICK, Farm Supt."

Address for circular, **Vt. Farm Machine Co., Bellows Falls, Vt.**

Made to sell at Highest Price; will take Premiums. Dairy Receipt-Book free. Address, Mrs. B. SMITH, P.O. Box 1954, 72 N. Fourth St., Philadelphia, Pa.

to sell the celebrated cow fetter. It sells on sight. Warranted to make the worst kicking cow gentle to milk, in three days. There is nothing equal to it for breaking helpers. Retail price \$2. For further information send for illustrated circular to

H. J. SADLER, Sole Proprietor, Warren, Trumbull Co., Ohio.

INSTRUCTIVE. BEAUTIFUL. AMUSING.

CRANDALL'S BLOCKS FOR CHILDREN.

The Best Presents Ever Invented for Boys and Girls.

Crandall's District School.

Every child, and man and woman too, will laugh over this group of teacher and scholars in the "district school," and thousands of parents will recall with great delight their own

experiences in childhood. The grave "master," seated by the desk, with his "whisking stick"; the boys and girls with their books; the "little lamb" that has followed his young owner into the school; the "dunce" and his cap, and the altogether comical appearance of the whole company, make this one of the most attractive toys of Crandall's invention.

Price per Set, \$1.00; by mail, prepaid, \$1.20.

Crandall's Heavy Artillery.

The greatest amusement of the age! Recreation at home for all ages, and for all seasons! Crandall's Heavy Artillery is made up of a large Cannon, complete, which throws a 1½-inch Rubber Ball to the distance of 25 feet or more, and Sixty Blocks (Red, White, and Blue), to build up Fortifications, also a Company of Soldiers, with Officer and Flag, to garrison the Fort. The Game is to beat down the

Fort by the use of the Big Gun. Rules, Illustrations of a variety of Forts, etc., accompany each box containing the set, and the box is 18 inches long, 6 inches high, and 8 inches wide.

Price per Set, \$3.00. Expressage to be paid by the recipient.

Crandall's Wide-Awake Alphabet.

No more long faces and no more tears over A B C! Here we have amusement and instruction combined. Each box contains twenty-seven little men, each representing a letter, with arms, legs, and jolly faces. This set of Blocks is susceptible of more changes, and a greater variety of forms and combinations than any Spelling Block ever offered to the public. The Pieces are durable, the Letters plain, the Faces mirthful, and the Amusement afforded by them unlimited. They please while they instruct, and are a source of enjoyment to young and old.

Price per Box \$1.00; by mail, prepaid, \$1.30.

Crandall's John Gilpin.

This beautiful and interesting toy is regarded by Mr. Crandall as one of the best of his inventions for the little folks. It is made up of two figures, John Gilpin—whose highly colored dress is specially attractive to Boys and Girls—and his Horse, which intelligent animal performs a very important part in the illustration of Gilpin's famous ride.

Price per Box \$1.00; by mail, prepaid, \$1.25.

Crandall's Menagerie.

One of the most wonderful and amusing things ever brought out for the entertainment of children. The six animals composing the Menagerie are beautifully painted, and so arranged into 56 pieces in each box, that tens of thousands of most laughter-provoking figures can be made up with them.

Price \$2.00. By mail, prepaid, \$2.50.

Crandall's Alphabet-Blocks.

RED, WHITE, AND BLUE.—Tasteless, odorless, and water-proof. The letters are on red, white, and blue ground. All children are pleased with them.

Price 75 Cts.; by mail, prepaid, 90 Cts.

Crandall's Toy Horse.

Here is something that will make glad every little boy who gets it. The Toy Horse is about 6 inches in height to the tops of his ears. He stands upon a four-wheeled base, all ready to be set in motion by his owner. He is made up in pieces and can be taken apart and laid snugly away in his box.

Price 25 Cts.; by mail, prepaid, 30 Cts.

Crandall's Acrobats.

Full of fun and frolic, and most brilliant in costume. These are among the most fascinating and ingenious toys ever invented. The number of figures which can be made with the pieces in a single box is limited only by the ingenuity of the operator.

Price \$1.00; by mail, prepaid, \$1.20.

"Ye Hero of '76."

The great "Patriotic Toy." A fine old soldier in a brilliantly colored uniform, with cocked hat, staff, and flag, all put up in a neat box. The Hero is so constructed that he can be placed in almost numberless and amusing positions, and will delight the children everywhere.

Price 25 Cts.; by mail, prepaid, 30 Cts.

Crandall's Little All-Right.

One of the funniest and jolliest of the low-priced toys. The lively Little All-Right throws himself into a great variety of positions as he whirls around the "wheel." This toy can not conveniently be sent by mail. It is one of the latest things manufactured by C. M. Crandall. Ask the nearest Toy dealer for Crandall's Little All-right, hasten to buy it, and be happy.

ORDERS from the TRADE will be SUPPLIED on LIBERAL TERMS.

Good Times FOR BOYS and GIRLS.

CRANDALL'S CHINESE BLOCKS.

In this most attractive combination, Mr. Crandall gives us the original Building Blocks, with an entire Chinese Family, the various blocks and figures being brilliantly colored. With a single Box, which contains a Set, one can build Chinese Houses, Palaces, Pagodas, Gardens, etc., etc. Thousands of structures of the Chinese style can be made with a Box of these fascinating blocks and figures.

Price \$1.00; by mail, prepaid, \$1.25.

CRANDALL'S BUILDING-BLOCKS.

Can be made into forms of almost endless variety. The blocks are put up in neat, strong boxes, and a large sheet giving various designs of buildings, etc., accompanies each box.

Price—No. 3, 75 Cts.; by mail, prepaid, 90 Cts.

CRANDALL'S MASQUERADE-BLOCKS.

Making 300 different and beautiful Combinations of Pictures, which are in very brilliant colors. They are not injured by washing, do not wear out, and afford endless amusement.

Price 75 Cts.; by mail, prepaid, 90 Cts.

CRANDALL'S EXPRESSION-BLOCKS.

With Letters on one side, Picture on the other. The Alphabet is the key to the picture which, when complete, represents the inventor in Dream Land. These Blocks are water-proof, and can be washed if soiled.

Price 50 Cts.; by mail, prepaid, 65 Cts.

CRANDALL'S ILLUMINATED PICTORIAL ALPHABET CUBES.

These Cubes are gorgeously colored, and will make over 500 beautiful combinations or figures. They are water-proof, odorless, and durable; put up in handsome black walnut boxes; and are most attractive to both young and old—an elegant present for the little ones.

Price \$2.50; by mail, prepaid, \$2.80.

CRANDALL'S IMPROVED GYMNASTS.

Two jolly little fellows, attached to opposite ends of two bars, are made to perform the most laughter-provoking antics, and to throw themselves into the most unaccountable positions, by gently working the foot of the wooden frame through which the bars revolve. It is a low-priced toy, made on the principle of the "Little All-right," and like that one of Crandall's latest. It is not conveniently sent by mail, but for sale by most Toy-Dealers.

N.B.—If postage is not remitted with the prices, as above, the blocks will be sent by express at purchaser's expense.

Orders from the trade will be supplied on liberal terms.

BACK VOLUMES OF
American Agriculturist.

The publishers of the *American Agriculturist* can supply any of the back volumes of that paper from the Sixteenth to the Thirty-sixth. These volumes contain more varied and interesting information on all matters pertaining to the Farm, Garden, and Household, than can be obtained in books costing three times as much money. Price of each bound volume, at the Office, \$2.00; sent post-paid, \$2.30. ORANGE JUDD CO., 245 Broadway, New York.

A Trochar for Cattle-Men.

In June of 1872 we gave illustrations of a Trochar and Cannula to be used in ringing a bull, and on page 13 (January) and page 97 (March) of the *American Agriculturist* for 1873 (copies of which may be got from this office for 15 cents each) we described the use of this apparatus in relieving hoven in cattle. These articles have brought out a large demand for Trochars, and failing to find just the right kind among the makers of surgical implements, we have induced an establishment to undertake their manufacture. We give herewith a small engraving of the Trochar. These articles are now in the trade, and may be had of most dealers in agricultural implements. Those who can not get them from dealers can receive them from this office, prepaid, for \$1.00. ORANGE JUDD COMPANY, 245 Broadway, N. Y.

A COPPER BULL-RING,

2½ inches in diameter, of the most approved pattern, with screw-driver for putting it together, will be sent, prepaid, on receipt of \$1.00. Address

ORANGE JUDD COMPANY, 245 Broadway, N. Y.

NEW CHAMPION MOWER.

This peculiar Machine is unlike any other ever made, and is a new departure in the construction and mode of operating Mowing Machines.

The draft is light; in operation it is nearly noiseless; and its adaptation to various kinds of work most extraordinary. The operator has the most **PERFECT CONTROL** of the machine when at work. The knife will run at any angle, and in any position in which it can be placed. The machine will work with equal facility over stones, stumps, among trees, on heavy hill-sides, through gullies, over ridges, in swampy marsh and over bog; in the shortest and down grass, whether laying to or from the machine, and in the **TALLEST CROP** to be cut. The machine can be instantly adjusted while in operation to cut low, to take up lodged and very short grass, or to cut over rough ground, wherever it is desirable to cut the crop high; and both ends of the cutting apparatus may be carried entirely above the ground, at any distance, **FROM AN INCH TO ONE FOOT**. The bar may be lifted to an upright position to pass a tree, remove any lodgment, or to free the guards.

The machines can be **INSTANTLY THROWN OUT OF GEAR** and can be put into work in order in a moment's time, and without the operator leaving his seat or stopping the team. THE **WHEELS ARE WIDE APART**, to stride the swath, and leave the grass unmolested. The steady, uniform, and powerful movement of the knife is the crowning feature of success. There are but two small cog-wheels in the machine, and they are about the size of a dinner plate. There is no pitman and no gearing in the drive-wheels. The gear-lag is enclosed by one small disk or rim, perfectly protecting it from dirt. One of the great features of this machine is discarding the old style of quick running gearing, and consequently dispensing with the frame work, heretofore employed to carry the gearing.

WELL DESERVED AND CONVINCING TESTIMONY.

THE NEW CHAMPION never received a faint-hearted endorsement. We present a few tersely stated commendations:

"I cut over 100 acres of hay and grain one season, and it did its work perfectly."—J. SHELL, Evans Mills, N. J.

"I value the Noiseless Action, and its reliability in hard-cutting, among its highest qualifications."—J. COGESHALE, Middletown, R. I.

"It is a powerful cutter, very light draft, durable, and completely under the control of the driver."—TIMOTHY S. FORD, Lowell, Mass.

"It cuts through thick and thin; does not choke."—D. HODGES, Lawn Ridge, Ill.

"The new movement is the longest stride ever taken in Mowing Machine Improvements."—G. L. GOODRICH, Newburyport, Mass.

"It works like a charm. It is the most complete and perfect machine I ever saw."—THOMAS MONTEITH, Montclair, Mich.

"As to easy draft it can not be beat. I used but one horse on a two-horse machine."—S. N. SANDERS, North Sudbury.

"It excels all machines in use at present."—HENRY D. B. FREER, Gardner, N. Y.

"I did not have to throw the machine out of gear, or stop the team, to pass a tree."—ALBERT GRAHAM, Johnson's, N. Y.

There was no special effort made during the last Fair season to secure awards of Premium for the New CHAMPION MOWER. But wherever it was convenient for our agents to exhibit it they did so, always, however, for the purpose of presenting it to the attention of farmers, rather than for that of competing for the premiums. Yet it bore away from every Fair and Agricultural Exhibition at which it was present, with only one or two exceptions, the FIRST HONORS—THE RED RIBBONS.

For Descriptive Pamphlet address: Whiteley, Fassler & Kelly, The Champion Machine Company, and Warden, Mitchell & Co., Springfield, O.; and The Toronto Reaper and Mower Company, Toronto, Canada.

WARING'S Books FOR Farmers.

DRAINING FOR PROFIT, AND DRAINING FOR HEALTH.

By GEO. E. WARING, JR.,
Engineer of the Drainage of Central Park, New York.
CONTENTS.

LAND TO BE DRAINED; HOW DRAINS ACT; HOW TO MAKE DRAINS; HOW TO TAKE CARE OF DRAINS; WHAT DRAINING COSTS; WILL IT PAY? HOW TO MAKE TILES; RECLAIMING SALT MARSHES; HOUSE AND TOWN DRAINAGE.

He (the author) describes the action of draining upon the soil, the construction of single drains and systems of drains, the cost and the profit of thorough drainage, the making of tiles, and the reclaiming of salt marshes, treats sensibly of malarial diseases, and closes with a chapter which should be widely read, on house drainage and town sewerage in their relations to the public health.

A Book that ought to be in the hands of every Farmer.
Price, Post-paid, \$1.50.

ELEMENTS OF AGRICULTURE. A BOOK FOR YOUNG FARMERS.

By GEO. E. WARING, JR.

CAREFULLY REVISED.

CONTENTS:—THE PLANT; SOIL; MANURES; MECHANICAL CULTIVATION; ANALYSIS.

The foregoing subjects are all discussed in plain and simple language, that any farmer's boy may understand. The book is written by a successful practical farmer, and is full of information, good advice, and sound doctrine.

Price, Post-paid, \$1.00.

THE SANITARY CONDITION OF City and Country Dwelling Houses.

By GEORGE E. WARING, JR.,

CONTENTS: The Sanitary Condition of Country Dwelling Houses. The Sanitary Condition of City Dwelling Houses. Fludd's System for the Ventilation of Soil Pipes. Correspondence.

Price, post-paid, 50 cents.

The Handy Book of Husbandry.

Containing Practical Information in regard to Buying or Leasing a Farm; Fences and Farm Buildings, Farming Implements, Drainage, Plowing, Subsoiling, Manuring, Rotation of Crops, Care and Medical Treatment of the Cattle, Sheep, and Poultry; Management of the Dairy; Useful Tables, etc. By GEO. E. WARING, JR., of Ogden Farm, Author of "Draining for Profit and for Health," etc. New edition, thoroughly revised by the Author. With 100 Illustrations. 8vo.

Price, post-paid, \$2.50.

The Sanitary Drainage of Houses and Towns.

By GEORGE E. WARING, JR.

A clear and admirable exposition of the evils which result from defective drainage, showing how they can be remedied. Col. Waring is an experienced engineer, and discusses in an able and forcible manner the best methods of house, town, and city drainage. Price, post-paid, \$2.00.

Earth-Closets and Earth-Sewage.

By GEO. E. WARING, JR.

INCLUDING: The Earth System (Details).—The Manure Question.—Sewage and Cess-pool Diseases.—The Dry-Earth System for Cities and Towns.—The Details of Earth-Sewage.—The Philosophy of the Earth System.

WITH SEVENTEEN ILLUSTRATIONS.

Paper Covers, Price, Post-paid, 50 cts.

A FARMER'S VACATION.

By GEO. E. WARING, JR.

A series of papers describing and illustrating the life and methods of farmers in several countries. Profusely illustrated. Price, Post-paid, \$3.00.

Village Improvements & Farm Villages.

By GEO. E. WARING, JR.

CONTENTS: Village Improvements.—Village Sanitary Work.—Farm Villages.—Life and Work of an Eastern Farmer. The work is illustrated. Price, Post-paid, 75c.

Either of the above books sent post-paid on receipt of price by

CAUTION TO THE PUBLIC.

To avoid imposition, purchasers of Waltham watches will observe that every genuine watch, whether gold or silver, bears our trade-mark on both case and movement.

Gold cases are stamped "A. W. Co." and guarantee certificates accompany them. Silver cases are stamped "Am. Watch Co., Waltham, Mass., Sterling Silver," and are accompanied by guarantee certificates, signed R. E. Robbins, Treasurer. The name "Waltham" is plainly engraved upon all movements, irrespective of other distinguishing marks.

This caution is rendered necessary by reason of the fact that our cases are frequently separated from our movements and put upon worthless movements of other makers, and *vice versa*, thus affecting injuriously the performance of the watches and vitiating our guarantee, which is intended to cover only our complete watches wholly made by us. It is necessary also because it is so notorious as to be a public scandal, that there is great fraud in the metal quality of both gold and silver cases as now generally sold. We have demonstrated by frequent assays that many gold and silver cases offered in the market are debased from 10 to 20 per cent from the quality they assume to be. This is a fraud upon the purchaser, and accounts for the low price at which such cased watches have been sold.

"Eighteen carat" gold, such as the Waltham cases are made of, is as nearly pure gold as can be made and be durable. It contains 750-1000 of pure gold, and 250-1000 of alloy.

Sterling Silver (English Govt. standard) contains 925-1000 of pure silver, and 75-1000 of alloy. The Waltham Watches will always be found up to the standard represented.

For AMERICAN WATCH CO.,

ROBBINS & APPLETON,

General Agents,

NEW YORK.

For GRAIN CROPS, Seeding Down to Grass for Permanent Mowing Land or Pasture,

MAPES' COMPLETE MANURE

(for average clay loam or heavy lands).
(Ammonia 6 to 7 per cent, Phos. Acid 10 to 12, Potash 3 to 4.)

COMPOSED OF

PURE No. 1 PERUVIAN GUANO—Guaranteed—**PURE BONE**, finely ground and dissolved in Sulphuric Acid—

PURE DRIED BLOOD OR FLESH (12 to 15 per cent Ammonia)—

HIGH GRADE POTASH SALTS.

All finely ground and intimately blended.

In dry condition suitable for

DRILLING.

The practical success of this manure has been universal, and has fully equalled our expectations on all average Grain and Grass lands.

It has invariably equalled heavy dressings of barn-yard and stable manure, in effects on the **grain crop**, and even excelled them in producing a **luxuriant after-growth** of clover, timothy, and other grasses.—In one instance, three bags (600 lbs.) per acre have proved fully equal to "100 loads (500 lbs. each) of New York Stable Manure per acre."

Unlike a merely **stimulating** fertilizer, or one that produces a crop—through the presence of a **single ingredient** and at the expense of the strength of the land, this manure supplies **all** the required ingredients for the **complete development** of the crop and the improvement of the soil, as shown by the effects on the successive grass crops.

Combines all the advantages of a first-class Superphosphate (made entirely from bone), together with Peruvian Guano and High Grade Potash Salts.

Price per Ton, ready mixed.....\$50.00
" " Bag (200 lbs.), ready mixed..... 5.25

Price per Ton—in lots of two tons and over—mixed, in form of ingredients named above, shipped in their separate and original packages.....\$45.00
(Cartage (50c.) charged **only** on shipments of less than half a ton.

COMPLETE MANURE (Ville Formula)

(for light or sandy soils).

Adapted for Grain and Grass crops, on land requiring large proportions of Potash and less Phos. Acid.

Price per Ton, ready mixed.....\$52.28

All grades of **Pure Bone**—**Peruvian Guano**—**Chemicals**—**Potash Salts**—**Pure Bone** dissolved—**Superphosphates**, etc., supplied at published rates.

Send for descriptive Price Current—also Pamphlet on Farm Experiments by Prof. W. O. Atwater—mailed free.

THE MAPES FORMULA AND PERUVIAN GUANO CO.,

158 Front Street, New York.

Directions for Use and Analyses accompany each bag of Mapes' Complete and Special Manures.

INVENTORS

can have their inventions patented in the U. S. and in Canada and Europe promptly and at moderate cost, by addressing

Terms, Publishers' Notices, etc.

Subscription Rates of the American Agriculturist, postage prepaid by the Publishers: One Copy, \$1.60 a year; Two Copies, \$3; Three Copies, \$4.20 (\$1.40 each); Four Copies, \$5.20 (\$1.30 each); Five to Nine Copies, \$1.25 each; Ten to Nineteen Copies, \$1.20 each; Twenty Copies and upwards, \$1.10 each; Single Numbers, 15 cents, post-paid.—The above terms are for the United States and Territories, and British America. To the above add 14 cents extra per year for papers delivered by mail in N. Y. City, and for copies sent outside of the United States and British America, except to Africa, Brazil, British Honduras, the East Indies, and Mexico. For the last named five countries the extra charge is 38 cents per year, to cover extra postage; Single Numbers, 17 cents, post-paid. Remittances, payable to Order of Orange Judd Company, may be sent in form of Checks or Drafts on N. Y. City Banks or Bankers; or P. O. Money Orders; or in Registered Letters, such letters to have the money enclosed in the presence of the Postmaster, and his receipt taken for it, and the postage and registering to be put on in stamps. Money remitted in any one of the above three methods is safe against loss. Bound Volumes from Vol. 16 to 36 inclusive, supplied at \$2 each, or \$2.20 if to be sent by mail. Sets of numbers sent to the office will be bound in our regular style for 75 cents (30 cents extra if to be returned by mail). Missing numbers for such volumes supplied at 12 cents each.—Any Numbers of the paper issued for 21 years past, sent post paid for 15 cents each; or any full year, sent unbound, for \$1.60. Clubs of Subscribers can be increased at any time, at the club rates, if new members begin at same date as original club.

Premiums for State and County Fairs.—We would again remind those who make up schedules of prizes for State and County Fairs, of the fact that Books for the Farm, Garden, and Household, or

a year's subscription for the *American Agriculturist*, are among the most attractive and acceptable Premiums which can be offered. We invite correspondence upon the subject. Such premiums as we suggest, have, in past years, been offered at many Fairs, and have uniformly given great satisfaction of those who have secured them.

Every German Cultivator and Laborer on the Farm, or in the Garden, OUGHT to have the German *American Agriculturist*, and thousands of new subscribers are taking it this year. It contains not only the Engravings and all the essential reading matter of the American edition, but an additional *Special German Department*, edited by the Hon. Frederick Münch, of Missouri, a skillful and successful cultivator and excellent writer. No other German Agricultural or Horticultural Journal in America has been so long issued; no other contains so much useful information and so many engravings. Germans are a reading, thinking people, and know how to make good use of what they read. Many Americans supply it to their German laborers and gardeners; all would find it pay to do so.—*Nothing else can compete with it in cheapness of price for the same amount of material, engravings, etc.* because the expense of collecting and making these is largely borne by the American edition, and no separate office or machinery is required beyond German editors and the printers. Its terms are the same as the American edition, singly and in clubs; and clubs can be composed of subscribers for either edition in whole, or in part.—*Please call the attention of your German neighbors to this paper.* It will do much to help new comers to a knowledge of the system and modes of culture used in this country.

WHY Advertisers find it Advantageous to use the columns of the *American Agriculturist*. (1.) They here reach more active, wide-awake, enterprising, buying people, than through any other journal in the world. For a dozen years or more the actual circulation of this journal has averaged over 100,000 copies sent to regular paying readers—not specimen copies thrown around the country, nor mere "spurt" editions got out occasionally to talk about. By a system of exchanges among themselves, very many copies are read regularly by two to six or more families. The readers are the wide-awake, enterprising class who are on the look-out for improved articles of all kinds. The *American Agriculturist* has a large circulation among intelligent Professional men, Merchants, Mechanics, etc., who look to it as a guide for the care of their homesteads. The actual, bona fide, subscription circulation of the *American Agriculturist* is certainly greater than the combined circulation of any other seven or eight similar journals in the country, and probably greater than that of any other ten or twelve journals of like character. (2.) Each number is kept on hand a month at least, and tens of thousands of copies are preserved every month, by binding or stitching into a volume. (3.) The advertisements are neatly and attractively printed. (4.) Most important is the fact that none but good parties are admitted—no nostrum, no quack medicines, nothing deceptive in form or substance, is allowed in the advertising columns. Advertisers are not only thus in Good Company, but the readers know these rules, and they therefore have confidence in the advertisers, and patronize them far more readily. This fact alone makes the advertisements in the *American Agriculturist* many times more valuable than the same space in most other journals, even if it had only the same number of readers. There is scarcely another journal in all the country, not even among the "religious press," that is so strict in its rules as to the character of the advertisements taken.—The best proof of the value of this journal, is the fact that a large number of business men have constantly advertised in it for twenty years or more (and still do) because they find that it pays.

In Changing Your Post-office, always give us plainly the former P. O. as well as the new

one; and do it a month in advance. One number will probably go to the old address, as the mailing wrappers are written some weeks ahead. It is well to provide for having one number forwarded, when removing to a new P. O., if you have not given us at least a month's notice in advance of your change of address.

WHERE TO BUY.—A good Directory for procuring Implements, Seeds, Plants, Fertilizers, and many other things—from trustworthy, responsible parties, who have both the *ability* and *intention* to do what they promise—is constantly at hand in the advertising columns of this Journal. We aim to admit no other parties, and exclude medical nostrums, quackery, deceptive announcements, etc., in order to make the business pages, as well as the reading columns, a reliable source of information. It always pays to read all the advertisements through carefully; in doing this one can scarcely fail to get some new idea that will sooner or later come into account. In corresponding with advertisers, it is useful, in several ways, to always inform them through what journal you made their acquaintance.

An ATTRACTIVE CATALOGUE, finely illustrated, of **BOOKS on Rifle-practice, Hunting, Fishing, Boating, and Out-door Exercises generally.**—The rapid development of Field Amusements in this country, and the increased demands for Standard Books on these subjects, has induced the ORANGE JUDD COMPANY to establish a **Special Department of Books** on the above topics. They now have in press, and will publish in a few days, a Beautifully Illustrated Catalogue, entitled "*Sportsman's Library of Standard Books.*" The work has been prepared with great care, and embraces not only all their own, but other publications of any value and interest upon the subject referred to. Very many of the illustrations are drawn from life, and faithfully portray the points and characteristics of Game Birds, Fishes, Horses, Dogs, etc., etc. The Publishers are now prepared to supply the Trade, and individual purchasers, with any of the books included in the Catalogue, which covers the entire ground. They invite their friends and the public generally, to call and examine the books in this Special Department. Copies of the Catalogue, which is an interesting work of itself, can be obtained by the trade. (It will be mailed to individuals desiring it, on forwarding their address and a couple of 3-cent postage-stamps.)

Harris' Insects Injurious to Vegetation.—A new edition of this valuable work is now in press, and will soon be ready. It is magnificently illustrated with 278 fine wood-cuts, and eight carefully engraved steel-plates, of full-page size, containing 95 figures. It is issued in two styles, both finely gotten up, but in one the steel-engravings are beautifully colored by hand, and the work bound with beveled boards and red edges. Price of colored edition, \$6.50; plain edition, which is also elegant, \$4. Sent post-paid by Orange Judd Company, the publishers.

Silk is a wonderful product of insect industry. It seems like spun spider-webs, and indeed it is but little coarser. And when such a concern as the Nonotuck Silk Company, of Boston, make their whole business the manufacture of "*Corticelli Silk*" thread, it shows the marvelous adaption of nature's minutest creations to the wants of man, when intelligently taken advantage of.

Large Grain Receipts and Sales.—The comprehensive tables on page 245, condensed from a great mass of figures, are interesting this month; rightly studied, these tables are always instructive. Table 2 shows RECEIPTS of ten times as much wheat for a month past this year, as compared with 1877; the increase in flour receipts (110,000 bbls.) is equal to half a million more bushels of wheat. Corn, Rye, and Barley show similarly. The SALES of Flour, Wheat, Rye, and Oats are correspondingly greater this year. Table 3 makes a still more gratifying exhibit, running the comparison back for half a dozen years. Every bushel sent abroad pays debts, or brings gold, and by so much adds to our national wealth.—Reducing the flour to wheat, we exported, from January 1 to June 11, of Wheat, Corn, Rye, and Barley, 39,310,000 bushels, against only 14,772,485 bushels last year—an increase of nearly 25,000,000 bushels, or nearly 2½ times as much.

Buchan's Cresylic Sheep Dip.—"D. S.," Joilet, Ill. This sheep dip has for its base, a preparation of carbolic acid, which is fatal to insects. It is therefore used to cure scab in sheep, also to kill the ticks which infest them. A dipping in the fall is always advisable for every flock as a preventive, if not a cure.

Information About Sheep-raising.—"J. H. H.," Ligonier, Ind. Although agricul-

trists in general are remarkably free from selfish jealousy, and readily impart information about their business to novices, yet it must be remembered that business men have quite enough to do to attend to their own affairs without being called upon to give instruction to every one who may desire it. We can not, therefore, give the names of persons who are prominent in any particular branch of agriculture, who would not thank us for the overwhelming number of letters they would undoubtedly receive,—a veritable surprise party, and one of the most unwelcome sort. You will find all the information you want about sheep-raising—the best climates, soils, breeds of sheep, and management, in "*Stewart's Shepherd's Manual.*" Price \$1.50.

When to Use Lime or Ashes.—"J. M. P.," Vienna, Ill. They may be spread at any time in the fall or winter. Lime dissolves slowly, but most readily, in the coldest water. The potash of the ashes that may be dissolved out will be retained in the soil.

Fertilizers for Worn Out Land.—"S. R. L.," Ullin, Ill., and W. A. R., Delphi, Ind. Land so run out by wheat-growing as to be so poor that it will not grow clover, can generally be brought into good condition by using 200 to 300 lbs. of guano per acre, or of the Stockbridge or Mapes' rye manure, and sowing winter rye. When the crop is nearly ripe, plow it under; then sow rye again, and plow that under. If the second crop will grow without manure, don't use any, but save it for the crops to be harvested. As soon as the land is rich enough, sow clover; at first if possible, with use of fertilizers, as indicated for rye. Cut the first crop of clover, and plow under the aftermath, as then a larger mass of roots will have developed in the soil.

Let Cancer Doctors Alone.—It is greatly to be regretted that some, even of the religious journals, of the highest character, admit into their columns the advertisements (and "puffs," too,) of "*Cancer Doctors.*" We could say a good deal on this subject, and may do so if it seems to be needed by our readers; but will here only state that no heed should be given to a single one of these advertising curers of cancers, no matter how highly commended. A real cancer is a very rare thing; it is so marked that any good physician will know it; and all possible means of alleviation are understood, or easily accessible, to the regular medical profession, and the best advice is obtainable at regular rates. The Cancer Doctors (offering free to "clergymen and the poor," as they can well afford to do, a penny-worth of caustic, for the advertising they thus get,) grow rich on large fees from others. They easily persuade a nervous person that a colored spot, or eruption, or sore, or wen, is a "*cancer*;" they apply caustic, and remove it, and get the praise, and puffing, and notoriety, and patronage, arising from the reputation of having cured an actual cancer—which they have not done. They are generally shrewd enough to invent excuses for not curing a real cancer, when they happen to get hold of such a case. Cancers may sometimes be a little alleviated by a good, regular physician; it is not probable that a real cancer was ever cured. All the cures heralded are cases that needed no cancer doctor's application.

Milking-tubes.—"A Subscriber," who, when he "*blows up*," might give his real name, is surprised that we should recommend milking-tubes or machines, believing that the suction of the calf is the proper method of milking. He suggests introducing milk into the stomach through tubes as a parallel case, and that, therefore, the milk-tube is unnatural and improper. So we thought once, but a stubborn fact in the shape of a nervous cow with sore teats, and several pails of milk upset, and sore arms and shins, changed our views. The writer has been for a month past, and is now, milking all his cows with the machine, and has no objection to it, upon any account, but many reasons to rejoice that he was induced to test it, in spite of some reluctance.

Fowler's Sale of Jerseys, at Herkness's Bazar, Philadelphia, a few weeks since, disposed of some fine animals at fair prices. If the sale to come off this month at Cincinnati shall include as good animals as this, the breeders of that region will get some fine Jerseys. One feature of Mr. Fowler's sales, not too common, is that they are always actual sales, and are to be commended in that as setting a good example to those people whose auctions have compelled many to state in their advertisements that theirs were to be *bona fide* sales, as if the public expected the hiding-in.

An Explanation is desired by the owner of the stock mentioned in "*Among the Farmers,*" in the June number, under a "*third sale*," and as a "*closing out sale.*" His reasons for having some of the cattle bid in, were as follows: The sale was advertised in the *March American Agriculturist*, but by mistake the card

was omitted from the April issue, although the sale was in April; a correspondent wrote to another journal that the sale was to take place in March, and it was a stormy morning; for which three reasons many were kept from the sale; and, further, there was a serious sickness in his family, which prevented proper attention to the auction. So the owner claims that he was justified in the course pursued, and was endorsed by his friends.

Oil from Pea Nuts.—"W. J. D.," Red River, La. Pea nuts contain 30 to 40 per cent of oil, and yield besides about 53 to 63 per cent of cake, which is a very nutritious feeding substance. The process of extracting the oil is in no way different from that used in the linseed, cotton seed, or castor bean oil manufacture. The nuts are ground; the meal is put into hair-cloth bags, and these are pressed between heated metal plates in a very powerful hydraulic press. We can not give the cost of the machinery precisely, but \$1,000 will procure sufficient to work up 2,500 bushels per year. D. Kahnweiler, of 120 Center St., N. Y., would probably be able to give some information as to cost of machinery. A 6-horse power engine would be sufficient for a small mill.

Incubators.—"J. P. W.," St. Louis. The incubators which have been described in the *American Agriculturist* are patented, and any person who makes them without authority from the patentees would be liable to prosecution. Besides, these machines are so sensitive in their use that, unless perfectly well made, they would not be effective.

Cotton-Seed Huller.—"R. L. S.," Cheneyville, La. Kahnweiler's cotton-seed huller is a very effective machine, costing only a moderate sum in proportion to its usefulness, to any Southern farmer who wishes to use cotton-seed, either for a fertilizer or for feed. For use in oil-mills, it is a standard machine.

Nitrate of Soda for Grass.—"Subscriber." This is an excellent fertilizer for grass, either in spring, or for use immediately after cutting, and is beneficial on almost any kind of soil, though its effects are more conspicuous on light land. But the retentive power of the soil for it is so slight, that a heavy rain coming just after its application will wash it into a light soil beyond the reach of the roots. Moreover, it should be remembered that nitrate of soda has only one element of fertility—the nitrogen, in the form of nitric acid—and is entirely lacking in potash and phosphoric acid. For starting grass, it has no superior, but can not be relied on as an exclusive manure. "Now that an agency of the Peruvian Government has been established in this country for its sale," it should be obtainable at a low price.

The Prospect for Dairying.—"M. E. H.," Story Co., Ia. Good Western butter brings as good prices as any other in market, and an extra good quality always sells well. There are "*ups and downs*" in all branches of business, yet it is a fact that dairy-farmers make more money, and get it in a more regular way, than grain farmers. With good pasturage, water, and grass land, dairying is more promising than grain-growing. For grinding the grain, the "*big giant*" mill would be useful; and a plan of a dairy-barn, that can be made small or large, was given in the *American Agriculturist* for June last.

Connecticut Experiment Station.—Bulletins 12, 13, 14, and 15, have analyses from 117 to 143. It is evident that the New Haven chemists place the value of nitrogen, potash, and phosphoric acid at a much lower rate than do the manufacturers; for in all these 32 analyses, only eight have an estimated value equal to the cost. These are Peter Cooper's Ground Bone (two samples), Forrester's Potato Fertilizer, Peruvian Guano, G. W. Baker's Bone-manure, Rafferty & Williams' Bone-meal, and several samples of muriate potash. As some of these valuations differ materially from those of other good chemists, the basis of calculation should be given, when publishing reports adverse to men believed to be reliable; although there are some in the lot we should feel no mercy for.

Foot-Rot in Sheep.—"J. B.," Lawrence Co., Pa. Foot-rot in sheep is caused by a decay of the horn of the sole and crust. It becomes malignant and contagious when the products of the decomposition poison the adjacent tissues, and cause an acrid discharge which conveys infection to the feet of other sheep. To cure it, the hoof should be pared; all rotten horn cut away; the diseased parts dressed with some caustic substance, such as carbolic acid, or a strong solution of sulphate of copper, and the diseased animals kept in a dry, clean yard, or a fresh grass-plot. Infested yards or pastures should be plowed up, or left unoccupied by sheep, for at least two years. For fuller account of this disease, refer to "*Stewart's Shepherd's Manual,*" price \$1.50.

AMERICAN AGRICULTURIST.

NEW YORK, JULY, 1878.

Hints for Work.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

The Harvest. after all the promise of the early season, is not much above an average as to yield, although the acreage is larger. What may be the products of fall sown grain, can not be ascertained until the crop is threshed and measured. From general indications it cannot be expected that the sanguine hopes held in spring will have been verified. It is probable that the failures mostly result from the depredations of insects, and defective fertilizing, which, as a rule, happens every year.

The Hessian Fly has done much damage in early sown wheat. Experience has shown that the means for exemption from its depredations that have been most successful, have been the use of fine salt, at the rate of 6 bushels per acre, and fine lime, soon after the plants have become large enough to attract the fly; late planting, thorough preparation of the soil, and the removal of all rubbish and weeds; ample manuring of the soil so as to stimulate a vigorous growth, and abundant stooling from the root-buds, by which new spikes are thrown up in place of those injured; and lastly, by sowing only the most vigorous and hardy stemmed varieties.

In the writer's Experiments, the past season, the "Clawson," and the "Silver Chaff" wheats, sown on the 29th of September, and dressed with only 100 lbs. per acre of artificial wheat-manure (with 200 lbs. more in the spring), were completely exempt from the attacks of the fly.

A Clover-sod for Wheat.—No other preparation for wheat is so generally successful as a clover-sod plowed under early. This method, however, upsets the usual rotation in which clover follows wheat. But a good wheat crop is better than a poor rotation; and the clover may come with the barley after corn, following a crop of turnips, sown upon wheat stubble. If we can produce 40 bushels to the acre, it will pay to grow wheat even with some trouble.

What shall be done with the Clover-sod?—It may be considered that a good crop of clover actually adds to the future capacity of the land instead of exhausting it to any extent. This occurs through the large addition to the soil, of nitrogenous and other organic matters derived from the atmosphere, and fertility brought up by the deep-searching roots. To secure the most benefit, the second crop should be plowed under early in September, with the seed, which is not lost, but returns to us again as a new growth of clover, when brought to the surface by reploting. If a crop of seed is desired, we should encourage a large growth, by top-dressing it at once, and thus put the soil in the best condition for wheat.

Quack Grass.—Careless farmers are laying up a store of trouble for themselves in permitting their farms to become overrun with quack grass, *Triticum repens*; there is no more troublesome weed, and no other that increases so fast by neglect. But the July and August sun will be a match for even this weed if we give the solar heat a chance to roast its roots. The cultivator is a better implement than the plow or harrow; and a "grubber" with curved teeth, which tear out the roots and gather them on the surface, is the best kind of gatherer.

Summer Fallows, once so frequent, are now considered of questionable value. As a means of improving the fertility of the soil, they are needless, now that we can procure artificial fertilizers at a less cost than that of the labor employed in the fallowing, and can raise a crop of roots or green fodder, that will clean the land and pay for the fertilizer several times over.

Oats, is generally the last of the small grains to be harvested, and is frequently gathered too late. If left until over ripe, the grain scatters badly; and

the appearance of an oat stubble always tells how much is lost. If at all over-ripe for cutting, oats should be reaped early in the morning, and never handled in the middle of the day. The straw is sufficiently valuable for feeding to make it worth while to cut the crop before the straw is entirely yellow from foot to head.

Corn.—We have noticed that the most successful producers of corn are always the last in the field with the cultivator. To "lay by" this crop in July is too early. The weeds thus have unnecessary opportunity to grow and mature seed. It is a question if it is not best to thin out the stalks more than is commonly done; to grow the grain crop by itself, with but two stalks, or even one, in a hill; and that for fodder by itself, with the stalks as closely set as possible for thrifty growth.

Growing Seed Corn.—Any grain can be greatly improved by selecting the best each year, and continuing to plant this for several seasons. No other grain-plant that we grow has so many abortive ears as corn. If we can make each of these productive, the yield can be greatly multiplied. If any farmer wishes to experiment in this way, he might begin this month by thinning out the plants, removing suckers, and encouraging the growth of the seed, instead of a useless amount of the stalk and leaf.

Fodder Crops.—Repeated plantings of fodder-corn may yet be made. Golden millet has proved a very productive fodder-crop for planting early this month; and the new "Pearl millet" is worthy of a trial. Cabbages set out upon early potato ground will give one of the very best fodder-crops.... Nothing else is better for milking cows than

Roots.—For planting this month up to the 12th or 15th, ruta-bagas, or Swede turnips, are excellent. Imperial Swede turnip is a new variety, that has been recently imported, and has been highly commended as yielding largely. No better ground than that from which early potatoes have been taken, can be had. Sow in drills 30 inches apart on rich soil, with 3 lbs. of seed to the acre. For later sowing this month and next, the "Greystone" turnip is a very prolific new kind, recently imported.

Early Potatoes, in many places, have fairly escaped the dreaded beetle, and are making a good crop. They should be harvested as soon as ripe, lest wet weather cause them to sprout. A second crop may be made by planting the earliest kinds the first of this month. Of all the new sorts, none have as yet displaced the Early Rose.

Late Potatoes should be free from weeds, and beetles; to suffer the leaves to be cateu off is a permanent injury to the roots. Generally it is the latest crop of beetles which does the most damage.

Buckwheat.—For a late crop, or one to occupy a rough piece of ground that needs mellowing, buckwheat may be sown up to the 12th of July. Half a bushel to one bushel of seed per acre is needed. A new variety, the "Silver Hull," is a beautiful, prolific, and valuable kind. We have sown timothy and clover successfully, with buckwheat, in July.

Live-Stock.—During the press of work the care of the animals must not be neglected. Plenty of good food and pure water should be given with regularity; the latter is specially important and necessary for health. They should be protected from flies and other insect pests, sheltered from the extreme mid-day heats, and kept clean. The ordinary sanitary rules which apply to our own health should be observed in regard to them.

Sheep should have a change of pasture. They are then more contented, and thrive better. A large field will not graze so many as several small ones of the same aggregate size. Give salt at least once a week. For scours, give a tablespoonful of castor oil; if continued, give a teaspoonful each of prepared chalk, and essence of peppermint, in a cupful of water. For stretches, which is only indigestion, common when the pasture gets dry, give an ounce of linseed-oil with a dram of ground ginger.

Pigs.—A run on a good clover stubble will be very beneficial. When confined in yards and pens, bedding of clean dry sand, several inches deep, will be found better than any other litter. An occasional sprinkling of a solution of copperas about the

yards, or a good dusting with ground gypsum, will act as a deodorizer and disinfectant. Young pigs should be forced just now, as fast as healthy growth will permit. Pork is advancing in value, and pigs may justly claim a little more attention than when it was worth but \$8 a barrel. Now is a good time to improve the stock. For November pigs, couple this month, and use a boar of some pure breed.

Poultry.—July chickens, if well cared for, will be large enough to go through the winter safely. After July we would set no hens, but set all possible up to the middle of the month. In the hot days of midsummer vermin breed very fast, and cleanliness alone will keep them in subjection.

Pests now run riot with the stock. The bot-flies are perhaps the worst. Wash their eggs from the legs of horses with warm water, or scrape them off with a knife. Protect cattle from their bot-fly, which lays its eggs on the loins, by rubbing a little crude petroleum on the backs of the animals. Tar sheep's noses to keep the sheep bot-fly from laying eggs in their nostrils. These means of prevention will add much to the comfort of the animals. By keeping stables clean and dark, the hateful black-fly (*Stomoxys calcitrans*), in general appearance so much like a house-fly, will be less annoying.

Notes on Orchard and Garden Work.

In former years we have suggested that if there was any time during the growing season in which the orchardist and gardener might "go a-fishing" with a clear conscience, it is during these months of July and August. It should be an especially favorable season for leisure this year, as—despite a few drawbacks—most of us have been able to keep well ahead of the work. To one whose work is always ahead of him, leisure never comes. In the term "going a-fishing" we include whatever takes the cultivator away from his "patch," and allows him to see what others are doing, and he may get quite as much recreation by fishing for ideas in the ponds and preserves of the orchards and gardens of other cultivators, as by the actual use of the hook and line. A week or two devoted to going among others engaged in similar pursuits—and this need not, of necessity, be very far from home—will give one a freshening up that will be worth more than all its costs, and the good influences of which will last all the year. To all who make use of the comparative leisure of mid-summer to visit the orchards, gardens, and ground of others, we have one bit of advice to give:

"Shut Your Own Gate Behind You!"

When you leave your garden, fruit patch, or grounds, of whatever kind, *shut the gate*, and leave whatever is behind it, there—don't take it with you. Recollect that when you visit the place of another, you go to see what *he* has to show, and learn what *he* has to teach. If you would be a welcome visitor, and be dismissed with a pressing invitation to come again, place yourself in a receptive mood; be for the time the attentive pupil and not the teacher. When others visit your place, will be the proper time to teach. Of all the intolerable bores who visit us is the man who brings his own place with him, and who, whatever may be shown him, at once institutes a comparison with his own, and at once begins to tell that "mine are much better than that,"—"I can beat you on so and so," and ignoring the thing before him tell us, "Ah, you should see my strawberries," "My roses," "My tomatoes," and so on all through—in short, the man who did not "shut his own gate behind him." Those who are so thoroughly satisfied with their own that they can not forget it for a few hours, should not visit, but remain upon the scene of their remarkable achievements—at home. We would not imply that one in visiting the grounds of another, may not, on occasion, drop a useful hint drawn from his own experience, or that he may not give his host any information that he may ask for. But we have been so annoyed at receiving visitors, and worse still, in visiting strange grounds in company with those whose only object in visiting appears to be to boast of their own affairs, that we

feel called upon to protest against it. Those who thoughtlessly fall into this unpleasant error, need only to be reminded of it, and they will sensibly avoid it. From the chronic boaster of his own achievements, we hope to be delivered.

The Benefits of Excursions

to other localities where others are following similar pursuits to our own, are not to be measured by the profitable hints we may pick up, but there is a mental and bodily relief that comes from a change of scene, which will allow one to return to the later work of the season refreshed, and with a spirit of content—for one who travels with his eyes open, can not fail to see that others, as well as himself, have their discomforts and drawbacks, and he is all the more disposed to meet his own with a brave spirit.

Orchard and Nursery.

On various occasions we have called attention to the value of early varieties of apples for a near market. This is a matter of special importance to orchardists in the Eastern States—indeed, to all fruit growers who live near large cities anywhere.

Winter Apples have a very long season, and if properly packed, may be transported for very great distances without any injury, and their slow ripening allows them to be stored for weeks or months. This peculiarity of late fruit allows the grower at a distance, where land is cheap, to compete with the orchardist near the markets. But with

Early Apples, the advantage is all on the side of the home market. Early varieties are short-lived—i. e., the period between the time when they are fit to pick, and that when they should reach the consumer is very short. Their general tender character does not allow of long transportation, as they are easily bruised, and soon fall into decay. For these reasons it is worth while for those who have orchards near large cities to consider the experience of the fruit-growers of Monmouth Co., N. J., and other localities near New York City. These gentlemen have ceased to compete with the orchardists in Ohio, Michigan, and other Western States, and find their profit in early fruit, of kinds which the Western growers can not possibly supply.

Care with Early Fruit is quite essential to success, and selection and neat packing are found to be as important with this as with any other fruit. The time when one would fill a wagon body with Early Harvest or Sweet Bough apples, put in a shovel and half-bushel measure, go to the nearest village and shovel up his fruit, has gone by. It pays to select the fruit, pack it in paper-lined new half barrels, or in baskets or crates, and put it upon the market as carefully as if it were pears or peaches. Thus treated, summer apples pay, as some growers know to their profit. Among the best and most

Profitable Early Apples, we enumerate the following, remarking that the list, as with fruit lists, will not answer for all localities: Benoni; Carolina Red June; Early Harvest; Large Yellow Bough; Primate, one of the best, but tender; Red Astrachan, tart, and excellent for cooking; Summer Queen, large and profitable; Tetofsky; William's Favorite. A variety locally called "Orange Pippin," is also very profitable in New Jersey.

Early Pears come to maturity rapidly, and if not gathered in time, many are apt to rot at the core. Selection and neat packing pay with these.

Thinning Fruit, however thoroughly it may have been done early in the season, will still need attention, and any excess may still be removed.

Young Trees.—See former months for the needed mulching, care against strangling with labels, etc. Much pruning may be avoided by occasional pinching the young growth, and removing entirely shoots that start where branches are not needed.

Blight.—We know nothing of this mysterious malady until the fatal blow has fallen. Cut away the lighted twig, branch, or tree, back to sound wood, and as a precaution, burn the dead prunings.

Insects.—It is not practicable to repeat every month and every year the whole insect story. In brief: *Borers* show themselves by "saw-dust," by gum, and by a flattened dead-looking place on the bark. Cut out or probe with wire....The

peach-borer is to be sought for just at or below the surface; the insect lays its eggs from now until autumn. A small mound of coal-ashes around the trees has been found useful....*Codling Moth*.—Pick up and feed to pigs all fallen fruit, or keep pigs in the orchard. Examine weekly the traps, whether of cloth or hay-hands, and kill those that have hidden there. Cloth traps may be run through an old clothes-wringer....*Slugs*, on pear, cherry, and other trees—little dark-green, slow-moving, slimy creatures—are killed by dusting lime, ashes, or even fine road dust....Late nests of the *Tent Caterpillar*, and those of the *Fall Web-worm*, now often abundant, must be destroyed wherever found.

Black Knot, often mistakenly supposed to be the work of an insect, should be cut out on its first appearance on plum and cherry trees.

The Time for Budding varies with the locality. Cherries and plums are ready first, and the pear next. The proper time is when well-formed buds may be had, and the stocks are in growing condition, so that the bark readily parts from the wood.

Fruit Garden.

Whatever is said on the general treatment of trees, and on insects, under Orchard, is generally applicable to trees in the Fruit Garden.

Grape-vines.—It was not necessary to give a special article on our "One Grape-vine" this month, the directions given on page 222 last month being sufficient for the treatment of the young vine. The growth this year of the new vine being preparatory only, all that can be done is to encourage the production of a single strong, vigorous cane. When the shoot has reached the top of the stake, let it hang over as it will. Keep the laterals pinched as there directed; pick off all beetles and caterpillars, and use sulphur freely if mildew appears.

Old Vines need similar treatment as to laterals, insects, and mildew. Chance shoots often appear on the arms, or other parts of the old wood. If these are not wanted, rub them off at once. But it sometimes happens that these come just where we would like to have a cane, to allow some change to be made in the training, such as to give us a new arm to replace one that is faulty; in such case we have only to encourage the new growth.

Summer Layering is an easy and rapid method of propagating the vine. As soon as a shoot of the present season, in a convenient place, becomes hard enough to handle—recollect that they break with the greatest ease at the nodes or joints—open a trench a few inches deep, and bury a few joints, removing the leaves from the buried part of the shoot; put down a stake, and turn up and fasten the end of the shoot to it, and treat this as if it were a young vine. In hot weather, and in light soil, it is well to lay a flat stone over the buried part of the vine, to keep the place moist.

Blackberries and Raspberries, as all cultivators should know, have biennial stems. The shoot which grows this season will bear fruit next summer; the stems now bearing fruit will die in the fall, to be succeeded by those now green and growing. Growers differ as to the propriety of removing the stems as soon as the fruit is off, some preferring to leave them until fall, under the plea that they will help strengthen the root. As good cultivators are equally divided on this, both parties claiming that practice warrants their view, we doubt if it is a matter of great importance, and would follow the most convenient course. New shoots, or canes for next year's fruit, should be cared for, and all that start, but are not needed, be hoed up as weeds. Raspberries may be stopped in their upward growth, by pinching, when at three or four feet, and blackberries at five or six feet. This pinching the tops will cause side branches to grow, which are to be kept in control by pinching when they have grown as long as desirable.

Black-cap and Purple-cane varieties do not throw up suckers at a distance from the old stool, but their new shoots start from the base of the plants, and these should be cared for as above suggested, as the branches that have fruited this season must be cut away in the fall, if not sooner.

Strawberries must be kept clear of weeds; if the single stool, or single row, method is adopted, then keep off all runners; if they are grown in alternate beds, then encourage the runners to take root in the intermediate spaces, to form a new bed.

Kitchen and Market Garden.

Notwithstanding this has been mentioned as one of the gardener's leisure months, it should, in one respect, be one of his most stirring months, so far as the soil is concerned. Those who wait until weeds need to be killed, before they set the cultivator, hoe, or rake, at work, lose much. Killing weeds is an important work, but is not the only good resulting from the frequent use of tillage implements. In a hard, compact soil, moisture readily finds its way up from below, and evaporates; if the surface is fine and loose, this loss of moisture ceases, and good cultivators know that a layer of loose soil is one of the best possible mulches. We have often advised the frequent use amongst the plants of a rake with long, sharp teeth; this allows of going over much surface that the cultivator can not reach, allows of rapid work, and besides being one of the most efficient weeders, leaves the surface of the soil in the best condition to resist drouth.

Asparagus.—See last month. The growth of tops will keep down all but a few coarse weeds, which should be pulled up as they appear.

Succession Crops will not be overlooked by those who would make the most of their gardens. Corn, Bush-beans, Beets, and Cucumbers may be sown.

Beets make in hot weather one of the best substitutes for spinach, and are sown by some for this purpose only; but we also keep up a succession of the Egyptian for their roots, as they are vastly preferable to late sorts.

Cabbages and Cauliflowers.—The late crop in the latitude of New York is set by the middle of the month. If to be worked by horse cultivator, make the rows three feet apart, and set the plants 18 to 24 inches apart, according to the variety. Examine the plants, and set none that have had roots, or have gone "blind," by injury to the growing point, or terminal bud. Set well down, and then press the earth firmly around with the foot.

Celery.—Around New York the main crop is set the first half of the month. Market gardeners have quite given up trench-planting, but set the plants on the surface in well-manured soil, and do not commence earthing up until the plants have made a large share of their growth. The dwarf varieties are grown almost exclusively. Ground that has been heavily manured for early crops of cabbages, etc., is laid out in rows three feet apart, and the plants set at six inches in the rows. Press the earth firmly around the plants, and keep them free from weeds.

Egg Plants, when fairly established, may be pushed with liquid manure every two or three days. Where potato-hugs abound, the plants have an almost hopeless "struggle for existence."

Squashes, Melons, and all of the family, are attacked by insects from the first show of the seed-leaf to the gathering of the fruit. Those which attack the foliage are had enough, but the borers, which enter the vine near the root, wait until the plant seems out of danger, and then bring it to a sudden end. Several advise covering the vine with earth for the first three or four joints from the root. More fruit is usually set than can be matured, and it is well to remove the excess. *Mem.*—Winter squashes, even when very young, are better for the table than any summer squash. Allow the vines of these to take root at the joints.

Sweet Potatoes need to be kept clear of weeds until they cover the ground. In northern climates, the vines should be prevented from taking root at the joints, which is easily done by running a rake or smooth pole under, and lifting them.

Tomatoes.—See last month for hints on supports. In field culture, the vines are allowed to spread upon the ground. Several have asked for directions for pruning tomatoes; the only pruning that we have found profitable (and we have tried the French system, where fruit is treated as if it were

worth \$1 each, instead of, as with us, 25 or 50 ets. a bushel), is that common-sense work which keeps the vine from becoming a matted thicket, and prevents them from being loaded with half-grown fruit when frost comes.

Insects on Tomatoes.—The potato-bug (Colorado) seems to be very freaky; sometimes it is a real pest on tomatoes, and again will leave them untouched. The worst enemy is the great sphinx caterpillar, as large as one's finger, which takes leaves, stems, and green fruit; wherever its coarse and abundant droppings are seen upon the ground, search for, and kill it. The horn on its tail is not a sting, and it can not bite the finger.

Turnips of the ruta-baga sorts, in the climate of New York, should be sown before the middle of the month. As soon as fairly up, sprinkle with air-slaked lime or a mixture of ashes and plaster. Cultivators differ as to transplanting in field culture, but in family gardens it is often desirable, to fill places that would be unoccupied. We know of none equal to the Long White French, for home use.

Odors and Ends.—Root crops of all kinds are usually too much crowded; one well developed and quickly grown root is better than two or three starved ones....Keep the soil stirred between the rows until the leaves prevent....If seeds are saved, do not, as is often done, take the leavings, but select the seed melons, squashes, tomatoes, etc., from the earliest and finest....For late crops of Sweet-corn, etc., choose the early and quickly maturing varieties; any excess may be dried.

Flower Garden and Lawn.

The mowing of lawns is directed by some to be done once a week, which may or may not be proper according to the season. Like other garden operations, this is one requiring judgment; the lawn should be mown when it needs it, and no oftener, and it is not generally likely to need it during a long continued drouth....The main work here is to keep everything in good order, and most of it has been anticipated by the Notes of last and earlier months....Dahlias of varieties with heavy branches will do better with three stakes instead of one....A large share of the ornamental shrubs may be easily propagated from the cuttings of this season's growth set in sandy soil under a well shaded sash....Nothing is more unsightly than faded flower clusters left upon shrubs and perennials, and these should be always cut away as soon as they have done their best, unless seeds are wanted.

Greenhouse and Window Plants.

The plants left in the house, whether few or many, need daily care in watering, ventilating, shading, and fumigating....Plants that have been set out of doors, unless plunged, are apt to suffer from too much heat at the roots; the pots should be screened, by the use of boards, or by some other method....The roots in pots that are plunged may make their way through the hole at the bottom, and finding fresh and congenial soil will often grow so rampantly that when taken up in the fall the larger share of the roots are on the outside; these can not be cut away without a severe check to the plant, and its occurrence should be avoided by occasionally turning the pots to break off such roots while young....Only a few plants will bloom continuously, winter and summer, and carnations, roses, and others that are expected to flower in the window or greenhouse next winter, should have their buds removed as they appear....House-plants that have been turned out of their pots and set in the garden, will often grow during the season to a size that unfits them for their former use, and the better way is to start new young plants from cuttings to take their places....The so-called "Saucer System" of striking cuttings will answer most of the wants of the amateur in mid-summer. It is simply to take a dish that will hold an inch or so of pure sand, put in cuttings of new and tender shoots, and keep them exposed to full sun, and at the same time to keep the sand always—not moist, but "sopping wet,"—in fact, in the state of mud. Those who have never tried this will be astonished at the large share of cuttings that will take root. When rooted, pot off in small pots of good open soil.

Gold has been up to 101 1/2 and down to 100 1/2, closing June 13, at 100 1/2, as against 100 1/2 on May 13; 100 1/2 on April 17; 102 1/2 on January 12; 103 on December 12; 102 1/2 on November 12; 103 on October 12; 105 1/2 on July 12; 104 1/2 on June 12, of last year....Under very liberal offerings, favorable crop reports, and the pacific tenor of the European advices, prices of Breadstuffs have declined materially within the month, leading to extensive dealings, largely on export account (shippers buying Wheat, Corn, Oats, and Rye, quite freely), though closing weak....Provisions have been more active, but very unsettled as to values, closing for Hog products generally higher; Beef, weaker; and Butter and Cheese much lower. Eggs, which fell off considerably in price, closed more firmly....Cotton has been in more demand, and has advanced....Wool has been pressed for sale, resulting in increased depression, without stimulating purchases, which have been on a very moderate scale....Tobacco, Hops, Hay, and Straw, have been in quite moderate request at irregular figures....Ocean freights have been active, especially in the Grain and Provision interests, leaving off more firmly....Grain rates by steam to Liverpool closed June 13th at 8 1/2 (about 16 1/2 cts) per bushel; Glasgow, 9d.; London, 4d.; Bristol, 9d.; Hull, 9d.; the Continent, 8 1/2 @ 9 1/2; by sail to Liverpool, 7 @ 7 1/2; London, 7 @ 7 1/2; 1/2 bush. Flour to Liverpool, by steam, 2s. 6d. (about 60 cents 1/2 bbl.); by sail at 2s. 3d.; London, 2s. 3d., and by steam, 2s. 6d.; Bristol, by steam, 2s. 9d. @ 3s., and sail, 2s. 4 1/2 @ 2s. 6d. per bbl. Provisions by steam to Liverpool, 30s. @ 40s. per ton. Cotton by sail 1 1/2, and steam 1 1/2. Grain, by sail, for Cork and orders, at 6s. per quarter (8 bushels), and to Continental ports, 5s. 6d. @ 6s. 10 1/2; and from Phila. for Cork and orders, 6s. @ 6s. 3d., and from Balt. for Cork and orders, 6s. @ 6s. 3d. The following condensed, comprehensive tables, care-

fully prepared specially for the *American Agriculturist*, from our daily record during the year, show at a glance the transactions for the month ending June 13th, 1878, and for the corresponding period last year:

Bees.—The market for the past month has been very irregular, and trade has been dull. The weather has been very unpropitious. At the beginning of the month, the demand was light, and the receipts heavy, causing several hundred head to go over unsold from day to day, and a fall of a full $\frac{1}{2}$ c. $\frac{3}{4}$ lb. in one week, after considerable fluctuation. As the month passed, business became no better, and it closed at the lowest rates, with few buyers for poor stock, and no eager ones for good, and a generally lifeless feeling all round. The most active purchasers were the foreign shippers, who took all the best stock and a large portion of the second best. 29 car-loads of cattle were sold for shipment alive. The best grades sold for 10 c. $\frac{3}{4}$ lb. to dress 55 lbs. $\frac{3}{4}$ cwt., and 11 c. $\frac{3}{4}$ 57 lbs. The bulk of the stock offered, sold at 9 @ 9 $\frac{1}{2}$ c. $\frac{3}{4}$ lb. for fair natives; poor stock sold slowly at 8 @ 8 $\frac{1}{2}$ c. $\frac{3}{4}$ lb.

reports of live stock. After a brisk business, we note a falling off in demand and inquiry for all grades. Roadsters and trotters are getting to be out of the regular market, being animals of luxury, rather than of necessity in the present times. Foreign shipments for the week ending June 10th, amounted to 154 head, chiefly car-horses, for the London "tram-road" (car-routes). A number of good carriage-horses were shipped to England. Arrangements are being made to receive an importation of a number of pure bred French horses for Western breeders, which are looked for daily. Prices may be quoted as follows; light draft horses, poor, \$60 @ \$100 per head; coarse, heavy horses, \$90 @ \$175; fair trotting roadsters, \$200 @ \$300 per head; stylish carriage-horses are unsalable just now, and no quotations can be given.

Prices of Feed.

Bran, per ton.....	\$18.00 @ \$20.00
Middlings, per ton.....	19.00 @ 21.00
Ground Feed, per ton.....	15.00 @ 21.00

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations can seldom be repeated, when those who desire information on a particular subject can so cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the American Agriculturist, containing articles referred to in the "Basket" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.60 per volume.

Veterinary Education has a strong friend and worker in the American Veterinary College, New York. Its fourth annual report shows the Institution to be in a healthy condition. The live stock interests suffer enormous losses from lack of properly educated veterinarians, one of whom should be located in every county of America. There ought to be a score of such institutions as this, with a hundred students each, where now there is one. The American Veterinary College now stands on a footing comparing favorably with European institutions, and we wish it all success. A free scholarship is offered to each State Agricultural Society. For particulars address A. Liantard, 141 W. 54th St., N. Y.

The U. S. Entomological Commission.—When the last Congress authorized a Commission to investigate the ravages of the Western Locust, it was ridiculed by many papers, but the appointment of such men as C. V. Riley, of Mo., Cyrus Thomas, of Ill., and A. S. Packard, Jr., of Mass., indicated that the Commission meant business, and if any good could result from an investigation, the right men were set at it. Occasional Bulletins have been issued, giving to the public such facts as it was important to make known at once, and now the final Report of the Commission is in press. This, from the synopsis of its contents, which we have received, promises to fully justify the appointment of the Commission; and its value to the locust-ravaged States, and indirectly to the whole country, will far outweigh its cost. As the Government printing office sends out so many publications that no one wants, we trust that, now a really useful work is in hand, a liberal supply may be printed and distributed. When the Report itself comes

to hand we may have more to say about it; suffice it at present to state, that the labors of the Commission show that the Locust is not an evil against which we are powerless. In this, as in other cases, a full knowledge of our enemy, its mode of life, and, so to speak, its strategy in warfare, suggest the tactics to be employed in combating it. The mere knowledge of the fact that but little is to be feared from the locusts after their first year in a new locality, there being abundant natural causes to prevent their increase, is worth all the Commission has cost. The principal means for their destruction to be employed by farmers, aside from the encouragement of natural agencies, are: the destruction of the eggs, which may be done by harrowing, plowing, and especially by irrigating; the driving (which is quite practicable) and bruising, or crushing, or otherwise destroying young and wingless insects. Whatever destructive methods are employed must be directed towards the insect, either in the eggs or its larvæ or wingless condition, for when full-fledged but little can be done towards their destruction, though it is possible, to some extent, to drive them away from a particular field or locality. These matters, and many others, are discussed in detail in the Report, which is amply illustrated by engravings. The Report, so complete and exhaustive, is a credit both to the Commission and to the Government which authorized it.

"The Native Flowers and Ferns of the United States," by Thomas Meacham.

Boston: L. Prang & Co.—The house of Prang & Co., so widely and favorably known for the excellence of their chromo-lithographs, has undertaken to publish a work with the above title. As a rule, we do not notice works "published by subscription only," and not put in the general book trade, and only depart from our custom in the present case in view of the enterprise shown in the undertaking, and to express our wishes for its success. The work starts with a first series of 24 parts, each part to contain four chromo-lithographs, with descriptive text, and all to form two volumes. Should this first series meet with success, we understand that it is intended to continue it with others. No systematic arrangement is followed, each part already issued containing flowering-plants of different families, and ferns. A work which will give portraits of our native plants has long been needed, and though several attempts have been made in this direction during the last half century, they have all, from one cause or another, come to a premature end. The present work has elements of popularity: its engravings, being colored, are showy and attractive, and the text gives only a brief scientific description of the plant, but is mainly devoted to such popular talk as the subject suggests. The first two numbers, as might be expected in a new enterprise, show to the critical botanist defects which will be avoided in future issues, and, on the whole, offer promise of not only an ornamental, but useful series of portraits of our native plants.

The New York Horticultural Society held its regular monthly meeting, at their rooms, on Tuesday, June 4th. The semi-annual exhibition being so near at hand, but little was shown except a few very fine strawberries and roses. Any disappointment on this account, was offset by the lecture on the "Summer Management of Large Fruits," by Mr. P. T. Quinn, of Newark, N. J. The lecture, given without notes, occupied half an hour, and was replete with valuable information, clearly and tersely given. Among the points forcibly illustrated by Mr. Quinn, was the necessity for thinning fruit, the need of cultivating the orchard, and the folly of planting dwarf trees (in which, by the way, be encountered strong opposition); he denounced dwarfs without qualification, urging that standards only should be planted in the orchard. The tree peddlers, the men with the wonderful pictures, he classed as the most unmitigated humbugs—asserting that they had done more to discourage fruit-planting, than all other causes combined, as they not only supplied miserable trees when they did send them at all, but they were utterly indifferent to the correctness as to variety of those sent.

Is it the Feed, or the Breed?—"H. C. B., Lake County, Ind. It is not the feed that makes the difference in cows as to dairy qualities; although feed, of course, is needed alike by all. But what would make one cow fat, goes in another to make milk, and in a third to cream and butter. The same food that would make a good dairy cow yield 20 quarts of milk, and more than a pound of butter per day, would make a Shorthorn or Hereford fat for the butcher; and some cows will require much more food than others, to produce the same results. There are breeds, as the Dutch, and the Ayrshire, that have been for scores of years bred for the milk or cheese dairy, while the Jersey has been bred for a butter cow. Some native cows may be as good as any pure-bred, but out of 100 natives there may not be one such cow; while in 100 pure-bred cows there will probably be more than half of them equal or superior to the best na-

tive. A long course of breeding for a special purpose cannot fail to be more effective than haphazard breeding.

If H. M. B., of Waterbury, Ct., had looked on page 233 of the June number, he would have seen the reply to his question about "soot." Please look the pages through when desiring information, and you may save both yourself and the Editors much time.

Estimating the Weight of Animals, etc.—"C. & C. A., Del Norte, Col.

There are no certain rules for estimating the weight of animals or hay; these depend wholly upon the character of the things estimated, and which can only be judged of by an expert. A Texan steer could not be measured by the same rules as a Shorthorn or a first-class grade; nor could an ordinary hog be judged by the standard of a Poland-China or a Berkshire. So with hay; the rules are as various as the kinds of hay, its condition and the amount of pressure to which it has been subjected. The rules for hay in general use are as follows, for a ton:

Timothy a year in mow or stack..... 500 cubic feet.

Timothy from the bottom of stack..... 400 " "

Timothy newly stacked..... 700 " "

Clover stacked for some months..... 700 " "

Clover, new..... 900 " "

Timothy and clover, old stacked..... 600 " "

Timothy and clover, new..... 800 " "

Common meadow-hay, old..... 800 " "

Common meadow-hay, new..... 1,000 " "

These are approximations only, and would, at the best, only mislead a person who was not acquainted with the quality and proper condition of the hay. For cattle, the rules are just as arbitrary and uncertain, or more so, as the fineness of bone, "feel" of hide, amount of offal, age, and condition, are all items of consideration.

The Time for Cutting Wheat.—It is a fact first observed and made known by an English farmer and agricultural writer, Mr. John Hannam—recently deceased—and widely confirmed by many experiments during several years past, that the later stages of the ripening process diminish the proportion of flour and nutritive value of the wheat. The time to secure the best grain is when the kernel is still soft enough to be crushed, but is comparatively free from moisture, and breaks into meal between the thumb-nails.

Bean Weevils.—"N. L., Bellevue, S. C.

The history of this insect is, in brief, this: The weevil deposits its eggs in or on the beans when they are very young, and on the vine. The "worms," or maggots, feed on the bean, and when full-grown go into the dormant pupa state; they change to perfect beetles—for such the weevils are—about plating time. They appear to be more troublesome in the Southern than in the Northern States, but are increasing everywhere. Mr. White, in his excellent "Gardening for the South," advises to store seed beans in glass or earthen jars, closely corked, into each of which is poured a teaspoonful of spirits of turpentine. This, of course, affords no help for beans intended for food, as by the time the beans are ripe the weevil is usually full-grown and in the pupa state. If a whole neighborhood would burn their "buggy" beans, and procure a fresh stock of seed quite free from insects, they would be likely to escape the pest for a while, but so long as the insect is planted, so long may a crop be expected—and this kind of crop rarely falls.

Soil Analysis.—"H. L. B., London, Canada.

There is no "simple method of determining the proportionate constituents of soils." Chemical analysis can only be learned by long study and careful training; and only practised with accuracy by one constantly at work in the laboratory. To become a skilled chemist, one must have a thorough education at some good agricultural college, or scientific school.

Making Manure.—"A. A. R."

When manure is "fire-fanged," or overheated, the most valuable portion—the nitrogen—is driven off, although the mineral elements remain. To prevent overheating, it is not required to continually fork over the manure, but simply to compact the surface of the heap, and to cover it with a thin layer of earthen. Unleached ashes may be mixed with bone-meal, if care is taken to cover the mixture with plaster, or earth; and the action of the ashes will act upon the bones to reduce them to plant-food; but unless the earth or plaster is used, there will be a great waste of nitrogen from the bones.

Poisoning of Sheep by Wild Parsnip.—"E. A., Gervais, Oregon,

writes that he lost several sheep from poisoning by eating wild parsnips which grew in the pasture. The symptoms were dullness, ears drooping, eyes dull, often lying down, staggering gait, and avoiding the rest of the flock; death ensuing the second day. Others were saved by giving them a tablespoonful of saleratus dissolved in half a pint of warm water.—In nearly all cases of sheep poisoning,

either by parsnip (cow-bane), laurel, or other injurious herbs—in which the symptoms are generally as above noted—the immediate use of half a pint of sweet or linseed-oil will generally bring about a cure.

Harvesting Stock-Peas.—"J. H. C., Jr.," West Point, Arkansas. There is no difficulty in thrashing stock-peas. As harvested, they may be thrown on to a barn floor or a cleanly swept yard, and trampled out by horses; or they may be thrashed with the flail.

Large Yield of Butter.—"D. W. M. J.," Delaware Co., N. Y. 200 pounds of butter per year is a very fair yield for an ordinary cow. Many dairies do better than that by keeping selected animals and feeding high. A dairy in Illinois produces an average of 300 lbs. per cow, yearly, but each cow consumes 12 quarts of corn meal daily. It is not always that the high yields reported are profitable, but if we can turn 100 bushels of corn, costing about \$35 in Illinois, into 300 lbs. of butter, worth \$75 or more, there is profit in that. When much corn-meal is consumed, there is less hay eaten; the dairyman endeavors to induce his cows to eat all the feed that can be turned into butter. Grade Jersey cows are the best butter dairy cows, especially for quality.

Leprosy in Poultry.—"J. F. S.," The symptoms of this disease are as you describe them; a dry scale appears on the legs and spreads over the body; the fowls die in a short time, exhibiting dullness and mopeishness during the sickness. We know of no remedy. It may be prevented by careful feeding and giving the fowls, at frequent intervals, some such alternative and tonic as "Imperial Egg Food." Fowls require not only grain, but some animal food, plenty of green vegetables, sulphur, lime, and abundance of gravel or coarse sand; and last, but not least, plenty of pure water. Cleanliness is also absolutely necessary to health.

Bony Tumor on a Horse's Leg.—"C.," Lake Crystal, Minn. When the periosteum or covering membrane of the bone is bruised or injured, and inflammation is set up, there is an increased circulation in the part, which often develops a deposit of bony matter. This causes an enlargement of the bone, which is incurable. The only remedy is to prevent the deposit by drawing off the products of inflammation to the surface by stimulating applications which produce suppuration. As soon as bone is formed, nothing can be done, but to leave the blemish, as lameness rarely results unless the seat of the injury be the interior of a joint.

Farming in California.—"J. W. W.," Henry Clay, Del. The methods of farming in California are different from those usual in the East. The climate and other circumstances of that State make it necessary to adopt special ways of doing things which are described in no book upon agriculture. Of course the principles of the art are the same there as everywhere, but there are few people able to carry into practice any special method of farming, from a knowledge only of principles. To farm in California, or any other peculiar location, one must see for himself how it is done.

A Malformed Udder.—"C. W. C.," Blue Earth Co., Minn. Unless the malformation of the udder interferes with the milking, we would leave it as it is. A communication might easily be made between the forward teats and the quarters of the udder to which they belong, by means of a probe, and inserting a long tube to keep it free until the walls of the new opening were healed; but as the milk is all drawn off by the blind teat, there is no need for the operation.

Tobacco Stems.—"C. F. W.," Louisville, Ky. The ash is almost one-fourth potash. They also contain a large percentage of nitrogen, and are valuable as a fertilizer. The best way to use them is in the manure heap, where they quickly decompose. They are also cut into bits six inches or so long, and placed in the hill, where they are speedily converted into plant-food.

Oil Stoves for Summer Use.—When living temporarily in the city many years ago, we found it very convenient to have a gas-stove. In hot days it often happens that fire is only needed to "boil the tea-kettle," and perhaps a single hot dish of vegetables, both of which can be easily accomplished with the gas-stove, and the fire in the range allowed to go out—to the saving of coal and the comfort of the household. Whether the gas-stove is economical or not, no one having to do with gas-bills can ever find out. When we moved to the country, beyond the reach of gas-pipes, we attempted to find the same convenience in oil-stoves that we formerly had in gas-stoves, but soon gave them up. The oil-stoves of that day were crude affairs; they would smoke and give off disagreeable odors, unless constantly watched, and allowed but one article to be cooked at a time. Finding

them unsatisfactory, oil-stoves were abandoned as more "plague than profit." But fifteen years bring changes in oil-stoves, as in other matters, and this summer a new trial was made. Noticing the advertisement of the "Hot Blast Oil Stove," in our columns, one was procured and put into service. For an oil-stove there are two essentials—safety is the first to be regarded—next, efficiency, or a sufficient supply of heat. So far as safety is concerned, we can only judge on general principles, and from the structure of this stove we do not see how with safe oil—and only such should be used for any purpose—an accident can occur. During the short time it has been in use, the stove in its simplest form has been found to both boil and bake in a satisfactory manner, and it promises to be a useful substitute for the range in disposing of a large share of summer cooking.

Basket Items continued on page 273.

Sundry Humbugs.

We sometimes wonder if it is possible to state a matter so positively and emphatically as to preclude all further questioning. If we have endeavored to do this with any one thing, it has been the Wall Street business; if there is any virtue in "line upon line," it should be manifest here; for we have said our say over and again, month after month. Notwithstanding all that has been said, letters continue to come, inclosing circulars, and making inquiries, some asking if we include the sender of that particular circular in our general caution. For obvious reasons we cannot particularize in this matter. We have taken considerable pains to look into this Wall Street matter, and have invariably found that the senders of these circulars were not known to the regular business men of the Street, and were in no case members of the Stock Board. We advise our friends, and this advice is that of men who have passed their business lives in Wall Street,

TO LET ALL SUCH SCHEMES ALONE.

Inquirers seem to be equally persistent concerning a Secret Service concern in Cincinnati. It seems rather strange that any one could seriously consider such a scheme at all. Do those who propose to enter the employ of such a concern—provided it were all that it pretends to be—reflect that they are placing themselves in the position of paid spies? In most communities, if a man were known to be a "detective," he would be so thoroughly despised and shunned by his neighbors that the small salary he might (?) receive would be a poor compensation for being an object of public detestation, and pointed to as a paid spy!

Inquiries concerning the

U. S. SECRET SERVICE COMPANY

came to the Police Department of Cincinnati in such numbers, that it was found necessary to have a printed reply. One before us, bears the signature of the Secretary of the Police Department, and says: "The U. S. Secret Service Company is regarded in Police circles as a *fraud*, and is one of several such that have been established here under the guise of legitimate business, and which, unfortunately, through defects in our laws, we cannot reach."—This will be a sufficient answer to the many inquiries about the U. S. S. S. Co., received from all over the country, even so far away as Oregon. Lately the inquiries come concerning the "American and European S. S. Co.," of the same city. Upon investigating this, we received word from one of the officials that the police authorities would print their opinion in the form of a circular, which would be sent us in a few days. It will be safe for anxious inquirers to wait awhile.... In April last we devoted a large space to setting forth the operations of

CLARK & CO., "ADJUSTERS OF CLAIMS."

It will be recollected that the dodge was to send to the person addressed a slip of paper containing his name, and inquiring if the signature was his; with this show of care in identifying the person, was the announcement that he was "entitled to a certificate of gold mining stock valued at \$500," etc. The full particulars of the operation will be found on p. 127 (April), with an account of what befell Clark & Co. These "adjusters" and *truth* have just one quality in common; both, though

"CRUSH'D TO EARTH, WILL RISE AGAIN," and the adjusters have "riz," and are dispensing that

"mining stock," in blocks of \$500, as impartially as ever. It probably occurred to Clark & Co. that every one might not want mining stock, even if it were that of the celebrated—not to say notorious—"Silver Mountain Co."

Being "adjusters," they could adjust one thing as well as another, so they add another branch to their business, and pass around jewelry, "assorted," mind you, in nice little \$240 lots. But does any one suppose that Clark & Co. would send jewelry to the wrong man? Not much, for are they not adjusters! And they add just a small slip with a name upon it to the letter, and say, so cautiously, "We find the jewelry to be lawfully yours, if this is your signature." As we gave the mining stock letter in full, we will place on record this other choice specimen of

THE EPISTOLOGRAPHY OF ADJUSTMENT.

DEAR SIR—A claim for \$240 worth of assorted Gold Jewelry has been placed in our hands for adjustment. From investigation, we find the Jewelry to be lawfully yours, if this is your signature on the enclosed slip of paper. Return the slip to us, so we can compare it with your signature, and if found to be the same, we will send you the Jewelry. The money you sent was invested on the general average plan with the Manufacturing Jewelers' Association, which resulted in securing for you the Jewelry referred to. Our charge for adjusting the matter is 5 per cent, which is \$12. Please send us that amount, or, if preferred, you can pay it at the Express Office, after you have examined the Jewelry.

Respy

CLARK & CO.

There may be people who will be caught in such a trap; but they will find very little sympathy, as, to get what is alleged to be worth \$240 for \$12, they become partners in a lie by assuming as true, the assertion that they had sent money, while they *know* it to be false. What a very crooked and dirty business it all is, isn't it, Clark & Co., for you, and also that for the great instigator and prime mover behind you. In the Article in April last, we stated, that Clark & Co., and their twin brothers, Keyes & Co., and Russell & Co.—what a co-operative concern it is—could receive

NO MORE MONEY THROUGH THE MAILS,

except at a risk; it was somewhat surprising to see them starting up afresh within a few weeks. Upon inquiry at the proper quarters, we learn that the exclusion still continues, and that the few simpletons, or knaves, who forward them money, must do it through the Express. At least one reader is disposed to heed our injunction.

"FARMERS, BE CAREFUL WHAT YOU SIGN."

A farmer in Bergen Co., N. J., asks advice about investing in an invention, which will, among other remarkable things, "enable any one to produce New Potatoes, ripe Fruits, Berries, etc., all through the winter months."—The probability or possibility of the process, we do not now discuss; the point is, shall the farmer sign the contract? We say most *decidedly not*, as it bids him to grow "not less than three acres of potatoes, according to the process of the invention, each year for seven years in succession," to sell the potatoes, and to pay over to the inventor one-fourth of the proceeds, without deducting for expenses. It is safe to say that no possible advantage to be gained by the use of any process or invention can warrant the making of any such contract. In the agreement, the invention is spoken of more than once as a "patent." If a "patent," why the solemn agreement as to secrecy? as one can always get a copy of any patent for 50 cents!.... The Editor of a flourishing paper in Illinois, sends us one of the many sheets or catalogues devoted to advertising what they call "Novelties," but which are mainly

TRASHY AND FLASHY ARTICLES,

many of which are worthless, and others worse than worthless, as they are absolutely pernicious. This Editor is startled at the abundance and wide dissemination of the "cursed advertisements," as he properly calls them, and the fact that mere children of both sexes, of unsuspecting parents are known to have concealed in their pockets the vile articles advertised. He brings these to our notice, and hopes we will "devote a little attention to the matter." "A little attention!" good friend; we have devoted much "attention" to it these many years, and could tell more about it in ten minutes than you are likely to learn in a year. We have considered it in all its bearings, and are thoroughly impressed with its importance; but the trouble is, that it does little good to denounce such things on general principles; to be effective, we must name the man who offers corrupting books, devices, and appliances, and this would be the very thing that these chaps would have us do. They would get advertised in the very quarters, in the virtuous families of the rural population, the very places which they can but occasionally reach by their ordinary methods. So long as professedly decent papers publish such advertisements as the "Toll-gate," without learning upon what kind of a road that Toll-gate stands (it leads directly *downwards*, and is very *miry*), and other such traps for the unwary, stuff of this kind will get sufficient publicity without aid from us.

THERE IS BUT ONE SAFEGUARD

against this evil, and that rests with the parents. How many parents so treat their children as to have their per

feet confidence? We put the question directly to our Illinois editorial friend: was your father your best friend, the one to whom of all others you would first tell of some success, and to whom you would first go for comfort in some boyish trouble, or for advice when in doubt? Probably not, but it matters little now—but it matters greatly with *your own* boys whether their relations to you are such that they can have no secret, or think it necessary to conceal anything from you. The evil complained of is one that affects the peace and purity of the home circle, and it is just there that the remedy is to be found. Isn't it so, brother L.?... We have been expecting it, and it has come at last! The opportunity was so good that we wonder it has not been seized before. Here it is:

"A TIMELY WARNING—EIGHT HUNDRED TONS OF DEADLY POISON!"

is the heading of the hand-bill. Of course, this means Paris Green. And the account of the horrible things that may happen, and a general statement—with no particulars—of what has happened, is enough to make one give up potatoes for the rest of his life. But what good will it do to stop eating potatoes, and cease using Paris Green at this late day?—Not a bit—the deed is done—the world is in a bad way!—If it be any comfort to know our fate, read!—"Poisoned Blood is to-day coursing through the veins of thousands of people who do not, as yet, know the fact—but the awful truth will burst upon them by-and-by."—Now, where are we; or, rather, where shall we be when that bursting bomb-shell hangs us to hally-hack?—It is rather hard on the thousands of people who do not know it. After "piling up the agony" until it becomes actual mental torture, we become anxious, and we begin to wonder if it wasn't the potato that brought all the evil into the world, instead of the historical apple (*a pomme de terre*, instead of a *pomme de l'air*, so to speak). Let any one read this hand-bill, and the world will look differently to him. The boasted triumphs of our civilization, our telegraphs and phonographs, our telephones and microphones, become as nothing. Why have we graphs and phones, why Paris Expositions and Commissioners of Agriculture, if, when that "awful truth will burst," we are all at once to go to the how-ows! But out of all this blackness of darkness is there not a single ray of hope; has not our dark cloud just a bit of silver lining (or green-back—we don't mind, legal tenders being worth 99 cts.)? This despondent view comes of reading the thing only half through.—A "ray." It gives us a whole sunburst of hope. We read:

"BUT IT MAY NOT BE TOO LATE."

See how gently he lets it on—as Pat fired the cannon "aisy," so as not to hurt Mike, who held the iron pot over the nozzle, that the hall might not be lost—"May not be too late to use a powerful blood remedy, such as,"

"SUCH AS P * * * * S PILLS."

Hear them:—"We appeal to every lover of his race to spread the information contained in this hand-bill, with all possible haste"—which *we* proceed to do—in our own way. It is perhaps not just the way our down East friends would like, but it is the best we can do. "Let every Minister of the Gospel take it for a text and preach from it. Why not?"—"Why not?"—Well, the only reason that occurs to us just at this moment, is, that Ministers of the Gospel are not, as a general thing, unmitigated donkeys, and while they may show a want of taste, they have texts in a work which has answered tolerably for over 1800 years, and they haven't got to preaching from hand-bills yet.

Useful Additions to Our Rural Literature.

It is with pleasure that we announce that the already comprehensive list of rural books, published by the Orange Judd Company, is about to receive important additions. Those in the greatest state of forwardness are here noticed:

Talks About Manures, by Joseph Harris, M. S., Moreton Farm, Rochester, N. Y., author of "Walks and Talks on the Farm," "Harris on the Pig," etc., is the title of a new work now in press, and shortly to be issued by the Orange Judd Company, 245 Broadway, New York. In the series of "Walks and Talks on the Farm," and later in "Talks About Farm Crops," Mr. Harris has become so well known to the readers of the *American Agriculturist* that he needs no introduction to them. In the above-named series, he adopted a colloquial style, which, while it is too diffuse for the close student, is popular with many readers.

The assertion "I have done so and so," will arrest the attention of many, where the abstract statement that "so and so has been done," will be passed unnoticed save by few. The writer, who speaks in the first person, at once places himself on friendly terms with his reader, who, feeling that the teachings are for his special benefit, gives them a careful attention that he would withhold from the same matter presented in the usual form. In "Walks

and Talks," the author succeeded in conveying and in popularizing scientific teachings, and in presenting to the ordinary reader the results of scientific researches in a pleasant manner. One marked and useful feature of "Walks and Talks," etc., is the introduction of "The Deacon," a plain, old-fashioned farmer, slow to adopt new ways, but of sufficient intelligence to accept new views and methods when convinced of their value. The Deacon, by propounding such questions, and presenting such objections to scientific teachings as would occur to the common-sense farmer, became at once popular with the reader, as he usually proposed just such views as would occur to the average farmer, and put the author on his defence. Besides the Deacon, the Doctor and the Squire gave variety to "Walks and Talks." In "Talks on Manures," the readers of the author's former writings will meet his old friends, the Deacon, the Doctor, and the Squire, to which are here added young Charley, who contributes his share of the Talking. These persons go over the whole ground, from considering the general and important question "What is Manure?" through the methods of making, keeping, and applying it, to the choice of particular manures for special crops. The author makes great use of the experiments on manures by Lawes and Gilbert, at Rothamsted, England. In this he is justified not only by the intrinsic value of the experiments themselves, but by the fact that he was himself at Rothamsted when a large share of these were made. Having a personal relation to this important series of agricultural experiments, his accounts of them possess an interest which the bare results, as presented in tables, do not convey, and while the tables are given, the author's comments on them increase their interest and value. We may add here, that the most important tables recording the Rothamsted experiments, are presented in full; these are not, to our knowledge, accessible in any other American work, and these alone will be to many worth the price of the whole book. It is not often that the results of scientific investigations are presented in a manner so thoroughly popular, there being nothing in the work that may not be understood by the intelligent farmer or by his boys. To the author's large circle of readers we have no need to say more about the work—to others, we can commend it as presenting the teachings of modern science as sustained and illustrated by the best modern practice. Ready shortly.

Winter Greeneries at Home, by Edwin A. Johnson, D. D., author of "Half Hour Studies of Life," "The Live Boy," etc. The title of this work is fortunate; had the author called it "Window Gardening," it would have met with a doubtful welcome. In all our horticultural literature, there are no works so thoroughly unsatisfactory as those on window gardening. They are beautiful works to look at, being illustrated with fine engravings of plants, which "might, could, or should," but somehow never "would" flourish in the window-garden, in fact made up by persons with no practical knowledge of the subject. These works recommend a large share of the ordinary greenhouse plants, for window culture, while all who have had experience know that but a few of such plants are suited to the purpose. The author of "Winter Greeneries" is a clergyman, who for several years has found recreation in beautifying his study with plants; his work resulted in so much enjoyment to himself and his friends that he has been induced to tell what he did, and how he did it, in a little work, with the above title. "Winter Greeneries" implies, what all with much experience will admit, that the first and main thing to be aimed at in window-gardening is an abundance of green. Green vines, green trailers, and erect plants, with foliage of various shades of green, are in themselves always pleasing, and are within the reach of every one who has a window, no matter how unfavorable the aspect, or how unsuited the room to plants in general. If this work did not go a step further than to show how to accomplish this, it would be most welcome, but the author, after many trials, has learned that it is possible to add some flowers to the green, and gives a list of the select few that, if his directions for their treatment be followed, may be depended upon for winter bloom. Some may be disappointed that so few flowers are commended, but this, to our mind, is the most valuable feature of the book. In window-gardening, it is not what we would like, but what will like us—or rather our surroundings, that must direct our selection, and in this the work is an eminently safe guide. The book is not a mere dry set of directions, but its teachings are presented in the pleasant form of letters to some young ladies, who, having witnessed the author's success, have asked his instruction, and this allows a genial personality to pervade the work, and makes it withal readable, as well as instructive. It must not be inferred from this that the teachings are the less concise and practical; having years ago gone over almost every step of the same ground, we can safely commend "Winter Greeneries" as the best guide to successful winter-gardening, as suited to American homes, with our peculiar domestic surroundings, that we have seen, and we feel sure that those who follow its teachings

will reach a satisfactory measure of success. The work, which is now in press, gives engravings of the author's study, and other illustrations.

The Paris Exposition.

The International Fair now being held in Paris is worthy of the versatile, enterprising, industrious, economical French people. The *American Agriculturist* is represented at the Exposition, by Mr. George Houghton, who may have something to tell us a little later. We give below a partial list of the leading American exhibitors:

Auburn Man'fact'g Co., Auburn, N. Y., Agricultural Tools.
Adriance, Platt & Co., New York, Mowers and Reapers.
Aultman, C. & Co., Canton, Ohio, Agricultural Machines.
American Watch Co., Waltham, Mass., Watches & Mov'ts.
American Fence Manufacturing Co., New York, Fence.
Allen, R. H. & Co., New York, Warehouse Trucks.
Bay State Rake Co., Wintchendon, Mass., Hay Rake.
Baker, Walter & Co., Boston, Mass., Chocolate.
Bickford & Huffman, Macedon; New York, Seed Drill.
Baker, H. J. & Bro., New York, Chemicals.
Browne & Sharpe M'f'g Co., Providence, R. I., Machine Tools.
Brooks, Ezra, Hartford, Ct., Automatic Pump.
Bailey Wringer Machine Co., New York, Wringers.
Blake Crusher Co., New Haven, Ct., Stone and Ore Crusher.
Cortland Wagon Man'fact'g Co., Cortland, N. Y., Wagons.
Chadborn & Caldwell, Newburg, N. Y., Ag'l Implements.
Case, J. I., Racine, Wis., Agricultural Tools.
Crozier, L. S., Williamsburg, Kan., Cocoons & Reeled Silk.
Coates, A. W. & Co., Alliance, Ohio, Grain Rake.
Deere & Co., Moline, Ill., Plows.
Douglas, W. & B., Middletown, Ct., Pumps.
Dederich, P. K. & Co., Albany, N. Y., Hay Press, Horse Power Bale Machines.
Eagle Mowing Mach. Co., Albany, N. Y., Mowers & Reapers.
Fairbanks, E. & T. & Co., New York, Scales.
Farmers' Friend M'f'g Co., Dayton, Ohio, Grain Drill.
Farquhar, A. B., York, Pa., Threshing Machines, Horse Plows, Rakes, etc.
Gale Man'fact'g Co., Albion, Mich., Plow and Hay Rake.
Gillott, Jos., & Sons, New York, Steel Pens.
Globe Horse-Shoe Nail Co., Boston, Horse-Shoe Nails.
Howe Scale Co., Rutland, Vt., Scales.
Hill's Archimedean Lawn Mower Co., Hartford, Ct., Lawn Mowers.
Ivers, F., Cambridge, Mass., Buggies.
Jobson Harvester Co., Brockport, N. Y., Mowers & Reapers.
Lovell, Juo. P. & Sons, Boston, Mass., Air Guns and Pistols.
McCormick, C. H. & L. I., Chicago, Ill., Mowers & Reapers.
Mason & Hamlin Organ Co., New York, Organs.
Massey, G. B., New York, Revolving Boot-heel.
Nason Manufacturing Co., New York, Universal Pump.
Nonotuck Silk Co., Florence, Mass., Spool Silk.
Osborne, D. M. M'f'g Co., Auburn, N. Y., Mowers & Reapers.
Randolph, Theo. F., New York, Ditching Machines.
Remington, E. & Sons, Ilion, N. Y., Fire Arms.
Snyder & Bro., New York, Steam Engine.
Stratton & Cullom, Meadville, Pa., Hay Loader.
Stanley Rule & Level Co., New Britain, Ct., Rules & Levels.
Speer, Alex. & Sons, Pittsburg, Pa., Plows and Cultivators.
Studebaker Bros., South Bend, Ind., Wagons.
Stoddard, J. W. & Co., Dayton, Ohio, Ag'l Implements.
Sharpe Rifle Co., Bridgeport, Ct., Fire Arms.
Taylor Man'fact'g Co., Westminster, Md., Portable Engines.
Trump Bros., Wilmington, Del., Scroll Saws.
Taylor, B. C., Dayton, Ohio, Hay Rake.
U. S. Wind Engine & Pump Co., Batavia, N. Y., Windmills.
W. A. Wood Mowing & Reaping Machine Co., Hoosick Falls, N. Y., Mower and Reaper.
Wheeler & Wilson M'f'g Co., New York, Sewing Machines.
Wardner, Mitchell & Co., Springfield, Ohio, Mowers & Reapers.
Withington & Cooley M'f'g Co., Jackson, Mich., Garden and Farming Tools.

Treatment of Working Oxen.

These patient, useful, animals are much abused, as a general thing. A smart pair of oxen, well-trained, and well-fed, can do as much plowing and other work on a farm, as any horses that I have ever owned. What I mean by "well-trained, and well-fed," is to give them the same care that you give horses. Instead of leaving them standing in the yoke beside the fence or barn, to eat their dinners, put them into the stable and make them comfortable. Feed lightly in early spring, and when they have come into full working condition, give a bushel of ground oats every day, to a pair weighing 2,800 to 3,200 lbs. I consider ground oats much better than the whole grain. Many farmers have an idea that any one can drive oxen, but as it is most important with them, as with all animals, that they should be treated with uniform kindness. I think the best man on the farm should do this. Never drive with a club or goad, but with a whip, and seldom use it. Oxen can be guided by the voice. I trained one pair that would stop instantly at the word "whoa," start at one cluck, and at a second decided cluck, move off into a trot. Be firm, but kind, and you will find them returning affection; showing it pleasantly if any is manifested for them. Oxen can be made to grow, while working daily. It is economy to

keep two pair for doing the work that one pair can accomplish, by being on the go from morning until night, that neither may be overworked. I make each pair of oxen, on my farm, gain from \$50 to \$100 a year. If cattle can not be well fed, they ought not to be kept. I have enjoyed and been interested in oxen from boyhood, and on my father's farm, broke and trained many a pair of steers. Always bear this in mind, that animals are very apt to catch the spirit and temper of their masters, therefore try to keep good-natured when directing and controlling them.

B. C., Bennington, Vt.

Drilling Grain.

For many years, the only method recognized by leading English farmers, as suitable for planting grain, has been the sowing of the seed in rows by means of a drill; and the system is now coming into prominent use by our own grain-growers. That corn in hills will produce more grain than if sown broadcast, as for fodder, seems a needless statement to make, so well is it known. Why does not the same principle hold with regard to wheat and other small grains? It does, and only needs trial, to be as generally accepted. The accounts of the yield obtained from wheat drilled and cultivated like corn, almost surpass belief—one cultivator in California reporting the product of an experimental plot at the rate of 175 bushels per acre. It is well known that the yield of wheat-fields where drilling is practised, with the proper fertilization and culture, is often double, and even many times that obtained in ordinary practice. The principal difficulty in the way

Fig. 1.—DISTRIBUTOR.

of drill-planting in the past has been the lack of suitable machines. Now, however, there are several excellent ones, among which is the "Farmer's Friend Grain-drill," made at Dayton, O. The working parts of this machine are shown at fig. 2. It is made to sow both fertilizer and seed at the same time; and not the least of it is the arrangement by which it becomes a hoe when desired. This matter of hoeing grain is of as much importance as the drilling, and is to be compared with the hill-planting and cultivation of Indian corn. Figure 1 indicates a section of the arrangement for feeding the seed into the drill. The diagonal ribs distribute the grain very evenly. This drill can be made to sow corn, peas, beans, turnips, and mangolds, as well as the small grains, and also to distribute any fine fertilizer.

Fig. 2.—"FARMER'S FRIEND" GRAIN DRILL.

of drill-planting in the past has been the lack of suitable machines. Now, however, there are several excellent ones, among which is the "Farmer's Friend Grain-drill," made at Dayton, O. The working parts of this machine are shown at fig. 2. It is made to sow both fertilizer and seed at the same time; and not the least of it is the arrangement by which it becomes a hoe when desired. This matter of hoeing grain is of as much importance as the drilling, and is to be compared with the hill-planting and cultivation of Indian corn. Figure 1 indicates a section of the arrangement for feeding the seed into the drill. The diagonal ribs distribute the grain very evenly. This drill can be made to sow corn, peas, beans, turnips, and mangolds, as well as the small grains, and also to distribute any fine fertilizer.

Bee Notes for July.

BY L. C. ROOT, MOHAWK, N. Y.

In many locations the early part of the season has been very unfavorable to bee-keeping interests. The month of May, in Central New York, was cold and wet, preventing bees from securing the usual early honey from apple and other fruit blossoms. In most other parts of the State, bees have suffered severely. April was favorable, and many colonies were strong enough, and would have swarmed during fruit blossoms had the weather been propitious. At this writing (June 3d), colonies are not in so good condition as they were a month ago. I have found it necessary to feed my own bees regularly each evening to induce them to continue breeding, and in many cases to prevent starvation. In 1871 I was obliged to continue feeding until after the middle of July. I had 100 colonies, and many of them did not have a pound of honey until basswood commenced blossoming on the

20th of the month. I had fed so regularly that they were kept constantly breeding, and were very populous. Basswood, then, afforded an unusual flow of honey, and during the balance of the season I secured an average of 100 lbs. from each stock, while many who took little note of the early scarcity of honey failed to secure even a moderate yield. In most northern sections, the heaviest product will be secured during the present month. Boxes should be removed promptly as fast as filled and well sealed, and their places supplied with empty ones. If extracted honey is desired, an extra number of empty combs must be supplied, from which the honey may be thrown with the honey extractor as fast as filled. Box honey should be kept in a cool dry place. Extracted honey may stand in a warm room. Avoid the very common practice of allowing over-swarming. If movable combs are used, and swarms are allowed to issue naturally, open the hive after the first swarm issues, and clip off all queen cells *except one*, which will prevent after swarms. If *all* are removed, and a laying queen introduced, it will be found to be the preferable method.

QUESTIONS.—"What is Grape Sugar?"—"What is Glucose?"—"Is there anything objectionable or deleterious in their use, in connection with the production of honey?" ANS.—Glucose and grape sugar are the same thing, and are obtained from grapes, honey, starch, and other articles. As to the use of the ordinary grape sugar, which is used by brewers, and can be so cheaply obtained, for feeding bees, or any purpose, my experience has not been favorable. So far as the wants of the bees are concerned, I consider nothing better than pure honey. When feeding to stimulate breeding, if there is a scarcity of honey there is much danger of inducing robbing. For this reason, I prefer to feed a syrup, as heretofore directed, made of 4 lbs. of sugar to 1 quart of water. This answers every purpose in feeding the bees; besides it attracts pillagers very much less than honey.

WORKER AND DRONE COMBS.—"Will you give such information as will enable a novice to distinguish worker from drone combs?"—"I find that very many have trouble in readily distinguishing the different kinds of comb. It is a matter worthy of earnest attention, as in practical operations it is very essential. Figure 1 is an illustration made by the late M. Quinby, from a piece of comb, showing the different sizes of cells and the bees that are reared in them, which is very true to nature in the form of the cells and size of the bees. The small cells, on the right hand side of the engraving, are worker cells. It will be found by measuring, that there are five of these cells to the inch, or 25 to each square inch, on each side of the base. The eight small bees are the workers reared in these cells. On the left of the engraving are shown the drone cells, which occupy about 4½ to the inch, or about 20 to the square inch on each side of the base. The large bee at the bottom is a good

Fig. 2.—CLUSTER OF QUEEN CELLS.

representation of the drones hatched in these cells. Although not included in the question, it may be of interest to some, to state that the queen, shown in the center, is hatched in a cell of entirely different form and appearance, as shown in figure 2, which represents several queen cells (b, d, e) attached to a piece of worker comb.

About Medical Matters.

As it is hardly just to class these as "Humbugs," the frauds as well as the well-meaning, we treat them under a separate head. Some ten years ago we set down

ONE DOCT. R. H. BURNER,

from the reading of his stupidly ridiculous circular, as a chap to be avoided. It appears that said Burner has recently been at work in and around Hartford and New Haven, Conn. He was prosecuted awhile ago for some reason, but escaped through an imperfection in the indictment. But for all this, Burner does not escape pun-

Fig. 1.—DIFFERENT SIZES OF CELLS.

ishment; the "Hartford Courant" and other papers are after Burner with such a series of regular scorches, that he will not find Connecticut a profitable field for future operations.... A subscriber in Vermont sends a circular of somebody's "Restorative Remedies," for our opinion. The circular has four closely-printed pages. We read on the very first line, after the heading: "Dear Sir—We enclose you Dr. —'s prescriptions;

"A CERTAIN CURE FOR"—

and we had no need to read any farther. Whoever promises "certain cures," takes a contract that *he can not fill*. Medical men know of but one "certain cure." So far as is known, sulphur has proved to be a "certain cure" for the *itch*—and that is not in the true sense of the word a disease—it is merely an eruption caused by the presence of a minute insect, to which, as to many other insects, sulphur is fatal.... Frequent inquiry is made of us as to the efficacy of

ELECTRIC BELTS AND CHAINS,

which are now being advertised as generally as they were 20 years ago. There are questions much more important than that concerning the electric appliances themselves, which each one who writes us, should settle first.—"What is the matter with you?"—"Who besides yourself, has determined upon the character of your disease?"—"Who has decided that electricity is the proper remedy in your case?"—"If electricity is prescribed by a competent physician, what one of the several forms in which it may be applied, has he advised?"—"If the 'Pulvermacher,' or any other chains, are thus prescribed, get them. If any other appliance, get that.' We will not do or say anything to induce any persons who are really ill

TO TREAT THEMSELVES,

nor can we encourage those who imagine themselves ill, to putter with electricity or any other remedial agent. The great trouble with all this medical business, is, that persons who do not know whether their liver is inside of the stomach, or outside, [indeed, we once knew of a quack doctor who certified that a woman had vomited up a part of her liver—which she could no more do, than throw up her great toe], who have not the slightest idea of their own anatomy—the action of the organs in health, and what may result from their disease—the great trouble is, we say, that such persons assume that so and so is the matter with them, and then write to us to ask if this or that is good for them. Frequently they write that they have spent \$5, or \$10, on some stuff "warranted to cure," and getting no relief, they wish us to expose the maker of the nostrum as a fraud. Such people are all beyond our

help. No matter what we say, they will go on doctoring themselves and trying one advertised thing after another. Every sensible physician knows that it is a comparatively easy matter to treat most kinds of disease, but that it often requires all his skill

TO FIND OUT WHAT IS THE MATTER, or to make a proper diagnosis. All these secret remedies do harm, as they excite the imagination of the weak and nervous. Their circulars enumerate just the symptoms and feelings that those who are "generally out of sorts" are sure to have. The reader finds that his "case is described exactly," and it follows, as a matter of course, that the stuff is taken. Lawyers have a maxim, that "one who pleads his own case has a fool for a client;" and this is equally applicable in medical matters. We have known several eminent physicians who would never prescribe for their own families, but whenever wife or children were seriously ill, would call in another physician—this for fear that their judgment as to what should be done, might be warped by their affections, and that they might be restrained from using prompt remedies through sympathy with the sufferer. If those who know the most, are thus cautious, what recklessness for those who know nothing about sickness and remedies to undertake to treat themselves! We would say in all seriousness to those who

ARE ILL, OR THINK THAT THEY ARE:

If your ailment is such as attention to diet and abundant exercise—with it, may be, some simple tonic, of which every family has its favorite kind, will not cure, don't—please don't, write for our opinion about this or that advertised medicine. Medicine is of the least importance—the thing you need to know is—what is the matter; that being ascertained, the question of medicine is easily settled. Instead of writing us, enclosing circulars of wonderful remedies, go to the nearest physician, who is a physician—not avoiding one who happens to be young—and find out what—if anything—is the matter.

THINGS TO BE REMEMBERED.

1st. That there is no sure cure for ANY disease.—2d. That you can not possibly judge for yourself, or from what appear to be your symptoms, just what is the matter with you.—3d. That ANY "Doctor" who attempts to prescribe for you from your own description of your symptoms, is surely an unreliable quack.—4th. That similar symptoms are exhibited or felt by you, so far as you can judge, for very different diseases, and those requiring very different treatment.—5th. That different conditions of the system, of temperament, etc., in different persons, require very different medicines or treatment for the same disease, and this applies to sight and hearing as well.—6th. That medical advertisements, and circulars, and pamphlets, are mainly successful, by detailing certain signs and symptoms in such a way that the reader, if at all nervous or credulous, is quite apt to apply the descriptions to himself, or herself, and thus hundreds of thousands of people are led into doing, and really making themselves sick, when they would have got well if they had let the medicines alone.—Hence, 7th. Never read any medical advertisements, or pamphlets, or circulars, whatever. You never find them advertised in this journal, though we could get tens of thousands of dollars every year if we would admit them.

Science Applied to Farming.—XLIII.

Natural Strength of Soils, and Economy in Making Use of It.

Every one who has traveled through that part of Connecticut will remember the barren plains just north of New Haven. Large portions of this soil, if such a dry, drifting sand may be called a soil, are entirely devoid of vegetation. It comes nearer my idea of a desert than any other territory I am familiar with in this part of the country. With the aid of Dr. J. W. Alsop, of this place, and Mr. W. Balentine, of the Experiment Station, the experiments referred to were made on portions of the poorest of this sand. Fifteen wooden boxes, each one foot square, were filled with the sand and arranged in three series of five each. The boxes of each series were numbered I., II., III., IV., V. In the

first row buckwheat was sown; in the second oats, and in the third beans. To fertilize these, several solutions were prepared by dissolving the proper chemical salts in water. One of these contained all the materials which plants require for their food from the soil. This "normal solution" was the same as is used in the experiments in "water culture," previously described, and was applied to No. V. of each series. Another solution, containing the same ingredients, except that nitrogen was omitted, was used to water the plants in No. IV. A solution, with everything but phosphoric acid, was applied to No. III. of each series. Potash was in like manner omitted from No. II. Finally each No. I. received only rain-water. The plants came up, and grew. Those supplied with the complete fertilizer, No. V., were healthy, did well, and gave a fair crop. Where potash was omitted, No. II., the plants were about as tall, but thinner, and the yield of seed was only about half as large. Without phosphoric acid, No. III., the plants looked about as well, but the amount of seed was extremely small. Where nitrogen was left out, everything else being supplied, the plants were stunted, spindling, and sickly. They yielded almost no seed, and were in fact no better than those which had nothing but rain-water.

When the plants were ripe they were harvested,

thing else was furnished, the growth was no better than with rain-water. This soil could supply considerable potash and some phosphoric acid, but its stock of available nitrogen was extremely low.

This is exactly what was to be expected. This sand is composed of particles of stone of different kinds, which contain more or less of the mineral ingredients of plant-food: lime, potash, phosphoric acid, etc., much more than most people suppose. But there is scarcely any vegetable matter to supply nitrogen, or to hold it if it were supplied. What this soil wants first of all is water. Next to that it needs vegetable mould to hold the water it gets, to supply nitrogen, and to help it gather nitrogen from the air. Given moisture and the vegetable matter that muck, green crops plowed in, and roots could furnish, and it might supply a portion of the mineral elements of plant-food for a considerable period.

The natural strength of a soil is what it has to fall back upon after being reduced by cropping. It is practically constant, and depends upon the chemical and physical processes, that with the aid of air and moisture, warmth and frost, and growing plants as well, are continually going on in every soil. These agencies are active whether the soil is cultivated or not. Proper tillage aids them wonderfully; but still, without it, the avail-

EXPERIMENT WITH BUCKWHEAT AND OATS GROWN IN BARREN SAND, AND SUPPLIED WITH DIFFERENT FERTILIZING INGREDIENTS.

the roots being freed from sand by careful washing, and the different parts measured and weighed. The picture represents buckwheat plants of average size, from each lot. The table below gives measurements and air-dry weights of buckwheat and oats:

Plants Grown in Barren Sand, Fertilized with Different Solutions.

* $\frac{2}{5}$ Centimeters=about 1 inch. † 1 Gram= $\frac{1}{15}$ grains.

This sand evidently needed a complete fertilizer. The omission of each one of the more important ingredients of plant-food brought the yield down, but in very unequal proportions. In lack of potash, everything else being supplied, the crop suffered badly. Leaving out phosphoric acid injured it still more; while, without nitrogen, even though every-

ble stock of food accumulates so long as less is removed than is resupplied. It is in this way that fallow ground recuperates, and that virgin soils have acquired their richness. But what the soil will thus do slowly for itself, we may do for it much quicker by manuring. This strength is like a deposit in the bank, which we may draw upon slowly or rapidly as we will, but which will, sooner or later, be gone unless new deposits are made. Natural strength is like the interest on good bank stock. It comes gradually, uniformly; can not be drawn in advance; and if not drawn will be held in store for future use.

How Crops are Dependent upon the Food-Supply in the Soil.

The money we get from the bank, however, whether from checks on deposits, or dividends on stock, we can use to its full value without discount or restriction. But the crop can not make such unrestrained use of the plant-food in the soil. The crop has to do not merely with the supply of plant-food as a whole, but also with each of its ingredients separately. It is, I believe, a principle of military science that a fortification is no stronger than its weakest point. The crop can not rise above the level of the lowest element in the food-supply. If all come up to the required standard, and other conditions are favorable, a good yield is certain; but if any one falls below this standard, the crop must fall with it. Now this food-supply varies in different soils. It varies, not only as a whole, but in its different parts. Sometimes one

element, sometimes several may be lacking. A soil may have a proper texture, amount of moisture, and a full supply of everything the crop needs, except phosphoric acid, for example. Add phosphate in available forms, and the yield will be bountiful.

If I have made my meaning clear, it will be seen that the main point in economical manuring must be to economize what the soil can supply, and to add what it can not. The proper use of special fertilizers is to fill up these deficiencies, to bring the food supply into equilibrium. As Mr. Lawes says, "Soils were meant to be exhausted." That is, the material they furnish was meant to be used. The point is to utilize it most economically, and add what is needed to bring the most largely and permanently profitable results. W. O. ATWATER.

[It seems to us that the most valuable fact indicated by this experiment is, that by far the best results were obtained from the box where the complete fertilizer was applied: results which corroborate the experiments carried on for 8 years by Professor Stockbridge at Amherst. The results indicate that a portion only of the potash and phosphoric acid might be omitted from a fertilizer for such land; how much, and whether an addition of organic matter would help to render available the mineral ingredients of fertility in the soil, are questions worthy of further investigation.—ED.]

An American Agriculturist Experimental Farm.

Devoted to the Testing of New Theories, Methods of Practice, New Crops, Fertilizers, and Implements.—An Important Enterprise for the Benefit of Agriculture.

The Editors of the *American Agriculturist* have always been experienced farmers, gardeners, etc.; and their work and their farms have been largely experimental, for the good of their readers. "The Pines," especially, is a place well known to the public, as the source of much valuable information, derived from Dr. Thurber's trials of new ornamental and flowering plants, and small fruits, and his experience in cultivating the old as well as new varieties; which work will be continued with ever increasing benefit to our subscribers. Recently a gentleman connected with the business of the Orange Judd Company, out of his interest in the cause of good husbandry, has devoted a large farm in Orange County, N. Y., to experimental purposes, for the benefit of American Agriculture; the experimental work to be under the direction of one of the editors of the *American Agriculturist*.

This Experimental Farm is located in a charming valley, running north and south, between two low mountains—Skunnemunk and Lawyer's Hill—extending from the ridge of one to the summit of the other. The soil therefore varies from gravelly mountain-top and loamy hill-side, to alluvial meadows—thus offering an ample variety of conditions. There novelties in field crops and vegetables will be tested and their value reported; new theories as to methods of practice will be severely tried, and their virtues set forth or worthlessness exposed; systems of fertilization, manuring, or feeding crops will be thoroughly investigated, and results reported; various methods in the management and feeding of animals will be compared, and the results given our readers; new implements, which manufacturers may place in our hands for trial, will be carefully tried, and their merits—for the crops there cultivated, and on that kind of soil—will be judged, and impartially reported upon. In short, Our Experimental Farm is to be conducted as an experimental farm, in the interests of the great community of farmers and gardeners; and all of this experimental work will be carried on in connection with, and as farm practice. But let every reader of this remember that most farm experiments are the work of years, and that immediate results can be obtained only in a comparatively few cases. So do not expect too much of this enterprise, and we will try to give you all you expect.

From the mountains on either hand, numerous springs water the hill-sides and meadows. So leaky, indeed, were the mountain reservoirs, that drainage has been necessary, and is now going on, over a large part of the tillable land; but there are also dry ridges, where the dryest of dry-soil crops can be raised. The farm is especially fitted for stock-raising, and rather poorly adapted to grain crops. Stock-farming, therefore, will be the general aim of the practice, with sheep as a speciality. Crops raised for particular industrial purposes, will also be prominent in our practice and experiments, as being of great importance to American Agriculture. This year, as the farm is under course of improvement from the state of neglect it was found in when recently purchased by the present owner, the experiments will be necessarily restricted within more narrow limits than we hope will be the case in the future. Those now under way are as follow:

Experiments Now Going On.

Amber Sugar Cane.—2½ acres on a dry, loamy plain of recently plowed sod, manured with well-rotted compost, and 250 lbs. of superphosphate per acre; 2½ acres on a fertile, moist, clayey loam, thoroughly drained, stubble-land, planted to potatoes last year; manured with 250 lbs. superphosphate, 200 lbs. high grade sulphate potash, and 160 lbs. nitrate soda, per acre. This is to test the value of this crop for the production of sugar, in the East, it having been reported as quite successful in some Western States.

Corn.—9 acres on a moist, drained meadow. In 5 plots, manured with green stable-dung, chemical fertilizers in different forms and combinations, and one plot unmanured. Other experiments are with various combinations of chemicals on potatoes and grass, to be reported in due season.

A *Lysimeter* has been put in position on a field of deep, loamy alluvial soil. A bottomless box, strongly made of two-inch plank, and about 45½ inches square inside, and averaging 36 inches deep, was forced into the soil until its top was even with the surface; then a frame of five-inch timber was

LYSIMETER IN POSITION.

let down outside the box, so that its upper side was two inches below the bottom of the box. A plank bottom, six inches each way larger than the box, was then forced beneath the box, upon the frame, by means of jack-screws and picking out the earth before it with a sharpened stick; the inside was lined with galvanized iron; and after the bottom was placed in position, the iron of the latter was soldered to the iron of the sides. The bottom inclines 1½ inches from back to front, and an opening is left at the lower side, from which the water which percolates through the enclosed earth is collected in bottles. Room is left in front of the apparatus, by stoning up a cavity dug in the earth, to attend to its working. A rain-gauge is at hand to measure the rain-fall. This is the third *Lysimeter* in operation in this country—the first being that of the Sturtevant Bros., South Framingham, Mass., set two years ago; the second is at the Massachusetts Experiment Station. The difference between the amount of water in the rain-gauge and that gathered at the *Lysimeter*, shows the proportion which percolates through the soil—the remainder being evap-

orated through the vegetation or from the surface of the ground. By analysis of the water running through, the wastes of fertility by drainage are determined; and thus we shall be able, also, to study changes taking place in the soil under different methods of fertilization and culture, as the area within the *Lysimeter* will be treated the same as the field outside. In short, the *Lysimeter* is an apparatus for studying the relations of soil, air, water, and fertilizers; comprising important questions.

Secretary of Agriculture.

The to-do being made over the attempt of the person who is supposed to occupy the position of Commissioner of Agriculture, to have his office elevated to a Cabinet position, is a striking illustration of the estimation in which this great industry is held. Some, in their desire to advance the calling, would grant Mr. Le Duc's utmost wish, evidently supposing that with a bigger name he could do better work. Others decry the whole plan as an attempt at class legislation, and hold up the past and present history of the Agricultural Department as an argument against the principle. That the industries of a nation, by which the bread and clothing, and all material wants of its people are supplied, and property is accumulated, should have some representation in the government, seems too self-evident for argument. Commerce, which represents but a limited number of people, and has only to do with the transportation and exchange of the products of agriculture and manufacture, has its interests carefully watched over by the government, which, for its benefit, has a Consul in every foreign port. Manufacturing, because of the individual and combined wealth of its supporters, commands respect and legislation for its interests.

The sending of mail matter is considered of enough importance to require a position at the head of the government. The protection of the property accumulated by the industries has two representatives in the Cabinet. While Agriculture, in which over half of all the people of the country are engaged, producing all that manufactures, trade, and commerce, have to deal with, and the foundation of all that the government is supposed to protect, is placed at the bottom as of utter insignificance. Verily, it seems as if the world were made up backwards, so true is it that the least is considered greatest and the greatest least.

The Department of Agriculture has power and scope enough, as it is, to do all that Agriculture can ask. It only needs a man at its head who knows the demands of the situation, who is an agriculturist in experience, education, and sympathy; a man of broad, liberal mind, and of executive ability, such as is usually selected for equally important positions in other departments. Such a man has never yet filled the office, but instead, it has been used as a sinecure for political favorites, and to pander to the demands of empty-headed politicians whose constituents are so impecunious as to be bought with a package of worthless seed, or a book of stale statements called a "Report," of little value, to say the least. A man who buys seed for distribution, of dealers who would otherwise dispose of them to planters who wanted them, or spends large sums for objects which any intelligent farmer would know better than to touch, and who does nothing more, except to seek personal glory, is to be pitied that he can not see his own inability; and the criticism and derision which he and his department receive should be visited upon those who permit this state of things—the farmers themselves, whose place it is to demand proper representation in this department. Given a man to fill the position of Commissioner of Agriculture, and we would guarantee the expenses of his department for a year if it was not at once recognized as a power for good. The position does not want more power; it only needs a man who can use that which is now given it. If a Secretaryship shall secure such respect for the industry, that a man of the proper caliber would be appointed to its head, then give us the Secretaryship—but not before.

A Summer Cottage, Costing \$150.

BY S. B. REED, ARCHITECT, CORONA, LONG ISLAND, N. Y.

These plans are for an economical Cottage, for an occasional summer residence of a family of four

Fig. 1.—FRONT.

persons. It is suited to almost any place, either by the water, or on the mountain, where rest and recreation are sought. It costs scarcely more than a first-class family tent (which it is designed in a measure to supplant), and is far preferable, as it affords better protection and accommodation, and is more convenient and comfortable. It also admits of some of the home-like ways of living. Tents supply little comfort; their form necessitates a cramped, disagreeable position, with barren walls, and very small facilities for housekeeping. They sway and vibrate with every wind, and are intolerable in a storm. Out-door shade, so desirable in summer, is usually already provided by large trees. A single low tree, with extended branches, may shade several cottages, and serve as support for swings and hammocks for the young folks. In connection with the building, stationary fixtures for bedsteads, tables, etc., arranged to fold up when not in use, save largely in room and furniture expenses....**Exterior.** (figs. 1 and 2).—The upright boarding and battening of the sides, the figured gable barge, hooded projections, and steep roof, are appropriate in material and style. The building is set one foot above the ground, and the space below is inclosed by turfing around to the level of the sill. For better appearance, and to raise the floor further from the ground, an additional foot or two of elevation may be given,

Fig. 4.—BED CLOSED.

BED OPEN.

with increased hanking or terrace....**Accommodation.** (fig. 6).—The interior has two rooms and two closets. The front portion intended for the family-room is of fair size, with two win-

Fig. 5.—BUNK OPEN.

BUNK CLOSED.

dows in each of two sides, and three doors, as shown. A folding-bed is built in one corner, and

a large shelf between windows at A; sufficient room remains for a center-table, chairs, etc. The rear room, or kitchen, has two windows, an outside door, and a closet. A circular shelf and a stove are placed at the side of the closet. A hunk placed in the opposite end of the room, serves as a seat during the day, and for a bed at night. A table is hung against the partition....**Construction.**—The foundation may be of stone, or posts set in the ground. The floor timber is framed together—levelled on the foundation, and floored over, and the edges cut even with the sills. The upright frame of 1½ x 5-inch plank, and the plates 1½ x 6 inches, are then placed in position, with openings for doors and windows, as shown in figure 4. The exterior boarding, dressed on both sides, is then put on and battened. The roof is similarly boarded—with the center portion ceiled down, leaving an air space above. At the ends of this air space in each gable, are openings through the siding for the passage of the heated air from under the roof. Similar openings in the ceiling over the center of each room, lead into the air space. Each opening is neatly finished with lattice work. The roof projects 8 inches, and has a 3-inch marginal strip all around, with pierced barge in each gable, covered with pine shingles. The door openings are protected by shingled hoods resting on dressed trusses. The windows are neatly capped. Each window has battened shutters, with wrought-iron hinges and fastenings. The in-

Fig. 2.—SIDE VIEW OF SUMMER COTTAGE.

side framework (see fig. 3) forms the jambs of the doors and sashes, to which they are hung with ordinary butts. The intervening spaces show as panels. The inside partition is 6½ feet high, and has an 8-inch cap projecting mostly to the kitchen side; this cap strengthens the partition, and forms a shelf. The outside and partition doors are panelled; the others are battened and clamped. The kitchen closet has four shelves, and the other, or front closet, has one shelf and two rows of hooks. The circular shelf at the side of the kitchen closet is set level with the bottom of the sash, and has a sheet of zinc attached to its inner edge extending to the floor, protecting the surrounding wood-work from the heat of the stove. The table is 2½ x 4 feet, is hung to the partition, and supported on swinging braces. The bed frame is constructed of ceiling boards, as shown (see fig. 4); when opened, answers the purpose of a bedstead, and when closed serves as a closet for the bedding. The hunk (see fig. 5) is also of ceiling boards clamped together. These devices are easily made by any carpenter, are inexpensive, and answer their purpose acceptably. The outside has two coats of paint, of any desired color, prepared and applied in the usual manner. The inside is stained with oil.

Estimate, cost of materials and labor:

378 feet of timber, at \$15 per M.	\$5.67
2 sills, 3x7 in. 20 feet long.	1 ridge, 2x7 in. 20 feet long.
11 beams, 3x7 in. 13 ft. long.	2 perkins, 3x4 in. 20 feet long.
30 flooring boards, at 28c. each.	8.40
53 ceiling boards (dressed both sides), at 28c. each.	14.84
54 ceiling boards (dressed one side), at 28c. each.	15.12
53 battens (half round, 1½-inch wide), at 6c. each.	3.18
10 planks, \$3.30; 15 boards, at 28c. each, \$4.20.	7.70
14 bunches shingles, at \$1.25c. each.	17.50
6 sashes, \$6.00; 3 panelled doors, at \$1.15 each.	9.45
2 lengths of tile pipe, at 50c. length.	1.00
Hardware, nails, and incidentals.	16.14
Painting, \$25.00; carting, \$6.00.	31.00
Carpenter's labor, not included above.	20.00
Total Cost, complete.	\$150.00

THE MASSACHUSETTS EXPERIMENT STATION has been established in connection with the Agricultural College at Amherst, by a gift from a friend of agriculture. This College has already rendered most valuable service to the farmers of America by

Fig. 3.—INTERIOR OF FRONT.

its experimental work, as well as by the educated young men it has sent out to influence good husbandry. It has done much to investigate fertilizer questions; with it the Massachusetts fertilizer law originated, which example has been followed by many other States, resulting in an enormous saving to farmers against the frauds that were formerly practised against them by unprincipled dealers. Its experiments on crop fertilization, the beet-sugar industry, and the flow of sap in trees, have also been of great value. Yet all this work has been done at the personal inconvenience of its officers from love of the subject, who were only paid for the work of instruction, and have had very little pecuniary help from State or individuals, in the work. The investigations now undertaken by the Experiment Station at the College, are as follows: In cultivation of amber sugar-cane, and manufacture of sugar therefrom; testing the comparative feeding values of Southern, Western, and Northern corn; testing the purity of farm and garden seeds; on feeding stock with reference to the best kind and amount of

foods to produce particular results, and a Lysimeter has been put in operation, the same as that on the American Agriculturist Experimental Farm, referred to elsewhere. Experiment Stations and farms are capable of doing incalculable good to agricul-

Fig. 6.—FLOOR PLAN.

ture; and it is a great stigma on the enterprise of our farming community that they are not established in every State. While in Europe there are hundreds; here there are only two Experiment Stations,

Agriculture in the Sandwich Islands.

BY EDWARD BELLAMY.

The three main groups of Polynesia, the Sandwich, or Hawaiian, the Tahitian, and the Feejee, have within twenty years risen to a very respectable rank among food-producing countries. Each of the five larger islands of the Hawaiian group has a wet and a dry climate, a hot and a cold one, with the gradations between these extremes, all lying within a day's ride of any point. The trade winds blowing steadily all the year round from the north-east, bring the rain clouds which, impinging against the lofty mountain ranges, are precipitated in showers that clothe the windward sides of the islands in perpetual verdure; while the leeward sides, receiving only occasional showers from clouds which pass the mountain gauntlet, are very dry. But against drouths the "lay of the land" around lofty central mountains affords a remedy in the numerous streams which furnish, in most seasons, ample supplies for irrigation. The perfection of the climate is such that the language has no word answering to weather. The Hawaiians have climate, but no weather. In any given place the temperature and density of the atmosphere are nearly identical the year round, but if change be desired, any variety of climate can be secured by removing a few miles either up or down the mountains, or from the windward to the leeward side, or the reverse. On the uplands of Maui there is generally snow-halling to be had in the winter; and on the highlands of Kauai fires are needed in July. The hottest portions of the islands are, however, by no

the equator. The explanation is the wonderful equilibrium of the temperature, which renders crops which will grow there at all safe as those which could endure considerable variation in temperature.

The soil is uniformly reddish in color, being formed by the decomposition of volcanic rocks. In texture it is extremely dry and light, and even where rains are most frequent, mud rarely accumu-

lated as even to make it difficult for visitors to obtain enough fruit for their private use.

Although the lowlands are essentially tropical in their productions, the uplands are a temperate zone in which the crops of the north flourish. Excellent Irish potatoes, although not large, are raised on Maui, and wheat is successfully, although not extensively, cultivated in certain parts. But sugar

planting has hitherto prevented any proper attention to other branches of agriculture. Not only have the latter been at a standstill for a number of years, but they have even retrograded of late, owing to the withdrawal of capital from them, to put into the sugar business. Before the reciprocity treaty, which admitted Hawaiian sugar into the United States free of duty, the sugar-planters in the Islands lived on hope entirely, though in 1873, just before the treaty, the exportation reached 23,000,000 lbs. But the middlemen, the Honolulu merchants and money-lenders, to whom the crops were all mortgaged, were the men who made the money. The immediate effect of the treaty was to put a bounty of 50 per cent on all the sugar produced. At this time the business received an enormous impetus,

and at present is the principal commerce of the Islands; and its growth and manufacture the principal industry. The gross profit of the mills at once became 100 per cent, leaving them, after the enormous deductions for interest money and middlemen's expenses, a clear profit of half that. Plantations which were in a tolerable condition, at once began to roll up fortunes, while planters, who had been in a desperate state, were placed on the high road to wealth. There was a prodigious rush of capital into sugar-planting. Men sold all they

HOUSE OF THE NATIVE SANDWICH ISLANDER.

lates. Within an hour or two after the severest storms the roads are dry. The larger part of the arable land lies in broad alluvial strips running around the shores, and extending five, ten, or twenty miles inland. Above this region are extensive uplands, more suitable for grazing purposes, and then come the mountainous crests of the Islands, towering up ten to fifteen thousand feet in peaks, each of which is an extinct crater, from whose mouths the lands below were originally vomited forth. Extensive forests occur among the central mountains of each island, and also diversify the lowlands. They are usually so dense as to be traversable only with the assistance of the axe, and are broken by innumerable profound chasms and deep circular pits, which were active craters at a period in the islands' history when their surface was pimpled more thickly with burning volcanoes than is a small-pox patient's face with pustules. The trees in these forests are overgrown with masses of ferns and parasites which interlace and bind the whole jungle so as to make it almost impenetrable. Large tracts on all the islands have been devastated by lava flows, and lava fields stretching for miles are of frequent occurrence. Of course these do not offer very eligible sites for plantations, but still it is astonishing what extremely fertile soil this lava makes when broken up. It actually seems as if the cooking process to which it had been subjected had prepared it the better for agricultural operations. It is no uncommon thing to find the natives raising their sweet potatoes on hardly cooled lava, merely broken up a little, and mixed with volcanic ashes.

For fruit lovers these islands are a paradise. Oranges, bananas, cocoa-nuts, mangos, mangosteens, strawberries, guavas, pineapples, figs, tamarinds, chiramoyas, alligator-pears, and all kinds of melons, peaches, citrons, grapes, limes, Ohia apples, raspberries, are but some of the fruits and berries of these fortunate isles. The oranges and bananas, as well as the fruits generally, are of unusual excellence, and far from being difficult to cultivate, only ask to be permitted to grow. The proximity of the San Francisco market, and the close steam connections with that place, as well as Australia, are circumstances which point to the fruit-growing business as one of the most promising industries of the islands; but at present it is so unaccountably neg-

HAWAIIAN DRESS.—MALE.

means oppressive, even for out-door labor, owing to the constant breeze from the sea. It is difficult for the visitor to understand how a country whose climate is not so hot as that of the Northern States, can yet be so essentially tropical in its products, growing almost everything that can be grown under

STONE IDOL.—GOD OF AGRICULTURE.

lected, had, begged or borrowed what cash they could, and put the proceeds into a plantation. All other kinds of business suffered paralysis; everybody was anxious to share in the sweet harvest. Everywhere in the Islands, out of Honolulu itself, sugar is the only theme of conversation. It is like a gold min-

ing excitement, and indeed the owner of a plantation, in good running order, has something very like a bonanza. Under its stimulus, the importation has probably more than doubled, so that at present the amount of the annual subsidy paid by the United States government to the Sandwich Island sugar business is at least half a million dollars, and will probably reach a million a year in the next six years, for the amount of sugar-land under cultivation increases yearly by a large ratio. As to the planters, it is certain that the Treasury could not be bled for the benefit of a more genial, gentlemanly, and hospitable class of men, but perhaps the propriety of singling out any class of foreigners, however personally agreeable to be enriched out of the American public pocket, may be called in question. The advantage is so obviously all on the Hawaiian side, that it is certain the treaty never would have been made, but for a vague notion in this country that it was a preliminary step to annexation. But it would be cheaper to buy the Islands than to renew it for another ten years.

Should any one be moved by the brilliant returns of sugar planting under the treaty, to remove to the Islands for the purpose of engaging in it, the consideration should be borne in mind, that it requires three years to get a plantation into full paying condition, and that this would probably leave possible but three "treaty crops," as the planters call them, before the end of the six years of plenty, and unless these were exceptionally good, they would leave no great profit over first cost of land and mills. Moreover, although there are still great tracts of good cane lands unoccupied, especially upon the large island of Hawaii, the entire lack of roads and fewness of convenient shipping points on the coast, limit the number of really eligible sites for plantations. All transportation must be done by mule-back over rocky and break-neck paths; and if any railroads or good highways are built, they must be at the expense of the planters, the government is so poor.

Among the Farmers.—No. 30.

BY ONE OF THEM.

Connecticut River Meadows.

What is more beautiful than the grass? Certainly the people along the Connecticut should admire it. I thought in this eminently grass season that the fields in Bergen County, N. J., looked wonderfully well, and rejoiced in it as something to be proud of; but a sight of the luxuriance of the growth of June grass and Red-top in the pastures on the south meadows at Hartford, subdued any such feeling. I refer particularly to the meadows within the dyke protecting Colt's Armory, and that whole section of the town from the rise of the river. This land, like the whole of that interesting formation—the Conn River Meadows—was formed by the wash of the river, is prevaillingly level, and was over-flowed by the river once or twice annually. The stream being at these times exceedingly turbid, carried finely comminuted silt over the quiet expanse afforded by the meadows, and here it was deposited. This silt forms a most excellent soil, which will produce fair crops with little or no manure, though contributing regularly to the fertility of the up-land.

One usually observes, rather painfully, on luxuriant pastures, how that the last year's droppings cause a rank growth not relished by cattle, hence conspicuous; but there was very little of this, and certainly as vigorous and uniform a growth of grass as I ever saw. The superiority of the grass not now flowed over annually to that which is outside the dyke, indicates that the soil has been improving all these years, through the action of the air and its own gradual decompositions and changes.

Reclaimed Swamps.

Some time last year, I told the readers of the *American Agriculturist* something of Mr. Augustus Storrs' reclaimed swamp in North Mansfield. I have been there again, and instead of the bogs and tussocks, and roots, and heterogeneous tangle which the plows had ripped and rumpled, and the harrows had twisted and torn, there was a smooth

beautiful field neatly plowed, harrowed level and smooth, part of it seeded down with oats, and the part which was worst last year, nearly ready for a second corn crop. It seems almost miraculous. There were in places last year strips of sod cut by the plow, and turned over, which were tenacious enough to have held together, if a team had been hitched to one end of 30 or 40 feet, and I presume might thus have been hauled off the field. Now, that sod is nearly gone; in most places the ground is friable and mellow, a few clods and roots remain, and there were a good many sticks and stems of long-buried timber which the plows turned up. These, with the stones on that part next to the up-land, were being picked off, and a new drain, to cut off the springs at the foot of a stony slope, had been dug, and was being stoned up and partly filled with the fine stones off the meadow. A big wall has been built along this slope, to get rid of the stones; it is about 5 feet high, and from 6 to 9 feet wide. A wall-layer employed on the farm, builds from 7 to 9 rods of a single wall 3½ feet high in a day, assisted by one laborer—rapid work that.

Disk Harrows Again.

Mr. Storrs was trying the Randal harrow in the meadow, and it did capital work, especially upon those parts where a tooth harrow would tear up the not yet thoroughly disintegrated sods, and roll them over the surface. The operation of the disks is to hold a sod down, and at the same time to scrape or cut a slice of soil off from it—that is, when the sods are very tough. When, however, they are tender, the disks cut them up, and so disturb them as to prevent growth—either turning the pieces over, or scraping up the soil adhering to them. Several times harrowing will make mellow ground even of a green sward. On the tough spots the harrow had to be heavily loaded, so that with the driver the whole weight was probably equivalent to 300 or 350 lbs. This would have put the disks in above their axles if it had been in ordinary ground, but here they ran just deep enough to work well.

I have known and approved these harrows ever since Mr. Nishwitz put his first disk harrow upon the market through the agency of the New York Plow Company, though I have never used them upon my own farm, until this year, it being stony and rough. This year, Messrs. R. H. Allen & Co. sent out some for me to try, and report to them as to their comparative merits. We gave the harrows a very thorough trial, on all sorts of ground, and they have done exceedingly well. In the matter of actual pulverization, they do not work so well as the square-toothed harrows; but they make mellow soil, and do not tear up the sods; they cover broadcast grain splendidly, and leave the land level, and in good shape, with little sod showing.

Shorthorn Cattle.

Every time that I see a good herd of Shorthorns, I am oppressed with feeling that other breeds are not of very much account after all. Not that I hold this opinion, nor that anybody does, but the contrast between such a herd and the Jersey, and Ayrshire, and Devon herds is so great, and the cows are so broad, and straight-backed, and deep, square-bodied, and big-shouldered, and soft and mellow-hided, and so abundantly clothed with beautiful wavy hair, and have such prettily incurved horns, and carry their heavy bodies on such proportionately light limbs, and altogether are so high-bred in style, and so majestic in presence, both bulls and cows, that other breeds suffer in comparison. Mr. Storrs' farmers showed an eight months' old calf that weighed about 700 pounds; yet had been fed only simple food, with a daily ration of skimmed milk.

Clean Roadsides.

The roads throughout this country are so wide that the broad strips of neglected ground between wall and wagon track make the journey along many highways seem to be through a wilderness of low trees, bushes and briars, stones and rubbish. Now, my friend of North Mansfield is a naturally neat and orderly man, and this state of things, prevalent as it was in his neighborhood—and in whose neighborhood is it not prevalent, unless some lover of neatness and thrift has made a stir among the rubbish—distressed him not a little,

so he has kept his men at work along the roadsides whenever they have had spare time, hacking away with their bush-scythes, and clearing away whatever is unsightly, until one may now recognize land which he owns by the clean greensward which everywhere extends from the fence to the roadway. The small outlay will be more than recompensed in most cases by the strip of good grass land which is virtually added to the farm. I have such a strip—a short one, I regret to say—from which I get at least one cutting of good hay every year, and every man might do the same where the dust and wash of the road keeps the ground in good heart. Neglected roadsides and hedge-rows are nurseries for all the weeds that can pester a farmer; they are lodging places for mice and rabbits, skulking places for foxes and other vermin, and no good anyhow.

The Bush-scythe in the Pastures.

It is not alone by the roadside that the bush-scythe may be swung to advantage. Let the men get over the fence; not that most farmers will have the roadsides cleaned up first, but whether or no, there will unfortunately be a fence to get over. I heartily wish there were no fences, nor any need of them. This, though written in May, will be read in July, and that will be just the time when the bush-scythe will do the most telling and killing service. From the 1st, or better, the middle of June, to the 1st of August, the bushes may be cut to death very easily. Earlier there is so much of the stored vitality, which enables plants to push such vigorous growths in the spring, still left in the roots and stumps, that they grow right on after being cut down, with scarcely diminished vigor; and later the ripening wood and fresh stores of pabulum laid up for the next spring's needs, will so far have increased that the cutting will not be fatal. If we attack the enemy when his provender is lowest, "between hay and grass," victory will be pretty sure to perch upon our scythes.

Cutting Brush in Winter,

or early spring, has some advantages, especially where sheep, colts, or even calves, are pastured; for the succulent stems of briars and rose-bushes, white birch, and many other shrubs, are so much relished by them that the amount of feed is really greater; and they keep the growth down, in the case of sheep, to such a degree that many things will be killed in the course of the summer.

A Farm Lumber-yard.

One thing more before I leave Mansfield. With plenty of space along the road near his house and barns, where he could pile saw-logs, fence-rails, and posts, boards, and timber, Mr. Storrs actually bought an acre of ground for a lumber-yard. Here are the piles of plank for stone-boats and such like, for stable flooring, boards for all purposes, posts, rails, and old and new lumber, and timber of all sorts. Since seeing this yard, and the convenience of it, I have wondered at the rubbish which thrifty and good farmers suffer to accumulate about their houses and barns, and especially along the roadside near their houses. It is so easily and conveniently remedied.

FEEDING PORK.—Pork is now lower than it has been for 30 years, and the prospect for those who have many hogs is not agreeable. Yet it would not be wise to sacrifice good herds on this account. Those who have not, will find this a good opportunity to weed out their stock, and replace it with a better quality of animals in preparation for the time which is certain to come, when pork shall again bear a profitable value. The chief profit from pure-bred stock consists in its early maturity; and the fact that a pig of a well selected breed and properly fed, can be made fit for the barrel at less than a year old, makes it of far greater worth than one which requires two years to arrive at a salable condition. To keep only the best stock should be the aim of every one who rears animals for sale; and there is no better time to begin to improve one's stock than when the value is low, and it can be done at the least expense.

Talks on Farm Crops.—No. 17.

By the Author of "Walks and Talks on the Farm,"
"Harris on the Pig," etc.

The Doctor used to be a great advocate for hoeing early in the morning. A neighbor of his, a German gardener, was quite celebrated for raising large crops of cabbage, and the Doctor thought it was because he hoed while the dew was on, and he used to tell me this because he wanted me to rise earlier. All I can say is, that if anybody wants to hoe cabbages before sunrise, I have no objection. But I do not believe that the small amount of water they secure in this way is of much benefit to the plants. The hoeing, especially deep hoeing, is good, but the thorough use of a horse cultivator is better. And I do not see any special advantage in working horses before breakfast. If men and horses get a good night's rest, and are in the field by half-past six, prepared to do a good day's work, it is all I ask. If they are half an hour later in the stable, provided the time was spent in cleaning the horses, I should not object. And so at noon and night. I would rather the horses were thoroughly cleaned, their shoulders washed, the collars examined, and everything made neat and comfortable, than to have the men keep at work until after sundown. Men and horses that work early and late, are apt to loiter during the day. Fewer hours and livelier and more energetic work will be one of the features of our coming agriculture. I like to see a man work when he works.

"Never mind all that," said the Deacon. "I think you will admit that it is a good thing to stir the ground when the dew is on."

"Certainly," said I, "and it is a good thing to stir the ground when the dew is not on. Or rather, it is a good thing to cultivate and hoe and kill weeds. The weeds on many an acre of potatoes and corn pump up more water from the soil every day than all the hoeing you could do night and morning to cover up dew, would furnish in a month. The fact is, the water from a slight shower, or from the heaviest dews, rarely reaches the roots of plants."

"You need not tell me," said the Deacon, "that the dews and showers are of no benefit to the crops."

"No one doubts it," said the Doctor. "The dews and slight showers check evaporation. To a certain extent they give the plants rest. During a hot day, we all know that the leaves of corn curl up. The evaporation of water from the plants is greater than the roots can take up. But during the night, evaporation is checked, and the roots keep pumping up water from the soil, and in the morning the plants are full of sap. Probably the main reason why plaster is so beneficial to clover, is due to the fact that it checks evaporation."

"That is a new idea to me," said the Deacon. "We all know that plastered clover is full of sap in a morning, and the dew lies on it longer. I supposed the plaster attracted moisture from the air."

"Not it," said the Doctor. "It has no such power. But it has been proved that if you have two plants growing in vessels of water, and you put plaster in one and leave it out of the other, the one with the plaster will evaporate less water than the other. It is a very remarkable fact, and throws new light on the action of plaster as a fertilizer."

"It shows," said I, "that plaster is likely to be of far greater benefit on rich land than on poor land. And I think experience shows that the better we farm, and the drier the season, the more good do we get from the use of plaster on corn, peas, potatoes, and clover."

"I thought you would say that," remarked the Deacon. "You seem to have no faith in anything except draining, killing weeds, and making manure. And I will say this for you, that your underdraining has given you this spring a great advantage over those of us whose land is not drained. I have rarely known the land so wet."

"Why, then," said the Doctor, "do you not go to work and underdrain? The mere advantage of being able to plow a week or ten days earlier will more than compensate for the labor and expense of draining the land. Farmers cannot keep up

with the discoveries of the age, and avail themselves of the wonderful benefits to be derived from the use of artificial fertilizers, unless they drain the land wherever drainage is needed."

"Good," said I, "that is pre-eminently true; and it is also true that artificial fertilizers do very little good unless we secure good tilth. And it is impossible to secure good tilth if the land is not drained either naturally or artificially. When the land is drained, we are prepared to go ahead with our improvements. Our cold winters and hot summers give us great advantages."

"I would like to know how," said the Deacon.

"The winters are long," said I, "and this gives us time to make preparation for the busy season. The summer is hot and dry, and this gives us a grand chance to kill weeds. The autumn is long, and this gives us time to prepare for the sharp work of our late and short spring. But all this requires great promptness and energy, and no little forethought, and good judgment. There is one thing I am thoroughly convinced of—we must get our land ready for spring crops the summer and autumn previous."

"I do not believe in summer-fallowing," said the Doctor. "And you yourself, though you advocate the practice, seldom adopt it."

"All the worse for me," said I; "I have frequently sown land to oats or barley when it would have been far better for me to have summer-fallowed the land. I do not say the two crops, barley and wheat, will not bring in more money than one crop of wheat after a summer-fallow. But look at the difference in the condition of the land! Look at the clover after a good summer-fallow on strong, dry land, especially if you have used lime. But if we can not afford to summer-fallow, we can afford to fall-fallow. I have plowed some of my land three times this spring for mangel-wurzel. If I had plowed it twice last autumn, one plowing this spring would have made it in better condition."

"Yes," said Charley, "and the land that is plowed early in the fall, and well worked, turns up well in the spring, and is fine and mellow."

"Of course," said I, "much depends on the nature of the soil. It would be absurd to plow light, sandy, or mucky land as often as clayey land. The sandy-land farmer has many advantages over the heavy-land farmer. And this is particularly the case since the introduction of good artificial fertilizers at reasonable prices. I have both kinds of land on almost every field on my farm. It is something of a nuisance. The sandy knolls require more manure, and the clayey intervals more and better tillage. By a little planning, you can plow the heavy portions of the field in the fall, say in September, while the sandy portions can remain in grass and be pastured. Put three horses on to the plow, and turn the sod over, and then roll the land."

"I have thought," said Charley, "that I was pretty good at working and cultivating land, but every time I visit one of our nurserymen or market gardeners, I come home feeling that we have much to learn and still more to practice. 'Comparing ourselves with ourselves is not wise.' We certainly cultivate our corn and potatoes more thoroughly than people did twenty years ago. We have better cultivators, and use them more frequently. But still, as compared with our nurserymen, market-gardeners, seed-growers, and even with our best farmers, most of us are still clod-hoppers! We must wake up. We must have more faith in ourselves and in the soil. We must indulge in the luxury of thorough cultivation. We must have fewer clods to hop, and less weeds to hoe. We can farm better, and more profitably, if we only make up our minds to keep ahead of our work."

"Which sounds very fine," said the Deacon, "but how are you going to do it?"

"I can tell you, Deacon," said the Doctor, "how you can do it. Hire an extra man, and never let your horses be idle. Keep them cultivating, plowing, harrowing, and working the land whenever you have opportunity. Give your corn a good horse-hoeing each way, once a week, all through July. Cultivate the potatoes as long as it is safe to do so. Do not sow corn-fodder broadcast, but drill it in rows wide enough apart to admit the use of the

horse-hoe. The benefit will more than pay for the labor, and the appearance of the land after the crop is harvested will be almost certain to induce you to adopt a better general system of farming. As soon as a crop is off the land, plow it. No matter how clean it is, plow it. No matter how foul it is, plow it. You will find no lack of work for your teams. I go about the country a good deal, and while I sympathize with a man who is poor and behind hand with his work from lack of means, I have little respect for a well-to-do farmer who digs his potatoes in August and lets the vines lie scattered all over the lots until the next spring. It has a slovenly appearance. It is bad taste and bad farming. Why put off until spring any work that can be done to far greater advantage now?"

"If I did plow my land after digging potatoes," said the Deacon, "I would sow it to rye, and plow it under for manure next spring."

"Very well," said the Doctor; "I have no objection. Do what you like. Only do not let the land and the horses lie idle."

"If I plow the land," said the Deacon, "and sow nothing until spring, does it not lie idle?"

"Not a bit," said the Doctor. "It lies idle if you don't plow it. A weedy corn-stubble, or a potato field, left as though the hens had been scratching the potatoes out of the hills, has an idle loaferish look. But plow it, and make it neat and clean, and it looks as though it was up and dressed and ready for business!"

Lean Cattle for Europe.

Good news for American stock-breeders is the demand for live cattle by German and English farmers. Recently a ship-load of Western cattle were landed in Tönning, to be fattened on the rich pastures of Schleswig-Holstein. Relative prices of young stock there and in this country warrant the importation of these young lean cattle for the purpose. This cargo, numbering 322 head, 15 horses, and 46 swine, besides some fat cattle, horses, and swine for England, were purchased at Chicago, and were so well received by the German farmers that the vessel was at once sent back for another lot. "The ship arrived in the harbor under salutes of cannon and a display of flags, and hundreds of people lined the quay." There is also quite a demand in England for lean cattle and hogs for fattening; and in the embargo against the importation of live cattle at English ports, an exception is made in favor of those from America. This, together with the increasing call for finely bred stock from this country for Europe, argues well for our agricultural interests. The more our attention is paid to stock-farming, instead of such exclusive grain and other crop production, the better will it be for our farming. English agriculture dates its present advanced position from the beginning of heavy stocking of its farms and generous feeding, which added largely to the fertility of the soil, and caused a consequent increase in the yield of crops.

Wool and Mutton.

Wool is low; and wool producers look in vain for any hopeful sign of returning high prices. Threatened changes in the tariff cause uncertainty; which inevitably acts unfavorably upon the production of an important staple like wool. But with or without a tariff, we have no fear that wool can not be profitably produced in this country. We have an enormous business in manufacturing woollen goods, which must be supplied with home grown material. Not many months ago we gave some facts in this regard which have been widely republished by other journals and which will still be fresh in the memory of our readers. Those facts showed conclusively that, no kind of wool we could produce could go a begging for a market while the people needed carpets, blankets, and woollen clothing. We shall probably have to wait many years before seeing wool sell at a dollar a pound; perhaps it may never bring that figure again. But as a rule a sheep pays its expenses with its wool, and gives us a lamb as profit under the worst of circumstances. This ought to be satisfac-

tory. Further than this, the sheep husbandmen of this country must pay more attention to mutton: instead of being quite secondary, it should be of equal importance with wool; and when it is so considered, and breeding is conducted accordingly, the price of wool will no longer determine the absolute profits or losses of the business. Mutton production has been greatly neglected by our sheep farmers; but on the lower prices of wool, we trust it may take its due prominence, as the demand is increasing, and always brings a relatively high price. As in all cases "the best, pays the best," it is the business of farmers to choose that kind of sheep which will give the most and best wool, the highest quality of mutton, and which are sure and prolific breeders. Even in the far West, where wool should pay handsomely at 25 cents a pound, and where pasture is the cheapest, it is found to pay the best to infuse pure blood into the flock, thereby producing superior wool. How much more then should Eastern wool growers find it to their interest to improve their flocks so as better to meet the present difficulties.

Hints and Helps for Farmers.

BARN LADDERS.—Our frequent correspondent, L. D. Snook, of Yates Co., N. Y., sends some devices for barn ladders,

1. POST & PLANK LADDERS.

which, although not altogether new, may be fresh to many young farmers. Figure 1 represents two kinds of these. That upon the right hand consists of a plank fixed to the side of the building where needed, in which a sufficient number of alternate holes are cut, as shown, to serve as steps. Another method is to insert pins into a post of the frame by which the ascent to an upper floor can be made with ease. Or a ladder, as indicated at figure 2, may be affixed to the frame.

Fig. 2.—LADDER IN FRAME.

STONE GATHERER AND CLEVIS.—J. L. Douglas, of Belleville, N. J., sends a sketch of an implement for gathering stone and mellowing the ground (see fig. 4), which is made as follows. A plank 8 inches wide at each end, and 12 inches wide in the center, and three inches thick, is cut in the shape shown. Holes 3 inches apart are bored, and teeth, made as at figure 6, are fastened therein. The plank is secured to a tongue, and strengthened with braces bolted at each end. Handles are affixed to guide the implement when in use. The whiffle trees are provided with screw eyes and rings (fig. 5) at each end, where they are protected by broad bands of iron to prevent splitting. The implement, when drawn over the ground, gathers any stones that will not pass between the teeth, and can be made to leave them in rows so as to be easily picked up for removal. The teeth

are fastened in places by means of nuts in the screws at the upper ends, a washer being placed beneath each nut to protect the wood. At figure 3 is shown a clevis suitable for a plow, harrow, or stone-boat. It is provided with a swivel hook, fastened by a nut and screw.

A SPRING LATCH FOR A GATE—GATE POSTS.—"O. B.," Brumfield Station, Ky., sends these items:

The latch shown at figure 8 is made of hard-wood; is 2 feet long, 3 inches wide for 5 inches of its length where it enters the post, and one and a half inches wide for the rest.

Fig. 8.—HANDY LATCH.

It works between the upright bars of the gate, and is kept in place by pins passing through these, and seen at P. The other end works between short pieces fastened to the level bars of the gate at T. The spring, S, is made of locust or other tough timber, and is fastened to the two lower bars. A pin, marked 1, receives the force of the spring, and another marked 2, prevents the latch from going too far. The catch should be made of a piece of hard-wood 4 inches wide, 6 inches long, and 1½ thick, beveled at one end for half an inch. A mortise is cut in the post, an inch from its front edge, 1 inch wide and deep, and 4 inches long. The pin, 2, is placed so that the latch will enter the post ½ of an inch. The wood of the post between the catch and the mortise, is cut away with a chisel, and given the same

Fig. 4.—DOUGLAS' STONE GATHERER.

slope as the catch. This is shown at figure 7; the piece added to the post being shown by the dark shaded portion. An arrangement of gate posts, whereby any danger of sagging of the gate is avoided, is shown at figure 9. The blocks, A, and the sill, B, which is aided by the wedges, W, hold the posts rigidly, and enable them to support the weight of the gate.

SELF-BINDING HARVESTERS.—There is never a need for a thing but it comes to our hand through the skill of the inventor and the enterprise of the manufacturer. The development of the immense plains of Northwest Minnesota as a wheat-growing country, opened up a demand for a self-binding harvester, and the almost immediate supply of several different effective machines, gave a great impetus to wheat-growing on a gigantic scale. Fields of thousands of acres in extent are now frequent, and one Minnesota farmer is operating 76 of these machines the present season, the total capacity of which will be 1,500 acres per day. This is farming on a grand scale, only possible by the fortunate coincidence of immense tracts of fertile level land, and harvesters of this complete character. The moderate cost of these machines, however, should induce their use on smaller farms, or

Fig. 5.

their ownership by persons who will harvest grain on contract, the same as threshing is done.

Canning Fruits and Vegetables.

The process of putting up ordinary fruits in self-sealing glass jars is now so simple and well understood, that it is practised in almost every family. Those who readily succeed with peaches, pears, the various berries, etc., find that when they try tomatoes, green corn, and other vegetables, in the same manner, they fail altogether; and as the season approaches, we receive numerous inquiries about canning these articles. There is no secret about canning corn, peas, tomatoes, etc., but the trouble is that the process is not one that can well be performed by women, and with the ordinary appliances of the household. The treatment required by these make tin cans necessary, and involves a long boiling after they are sealed up. The Oneida Community, celebrated for the excellence of their products,

Fig. 6.—TOOTH.

long ago published freely every step of their process, and others have given accounts of the methods, and the more there is known about them, the more evident it becomes that the canning of certain articles is a distinct branch of manufacture that can no more be readily introduced into the family than shoemaking or weaving. The general routine is, to fill tin cans with the article to be preserved, and to solder tight. The cans are then placed in a boiler of water, or in a tank which can be supplied with high-pressure steam, and kept at the temperature of the water or steam for a certain length of time. This operation is called in the trade "processing," and much of the success depends upon the length of time each particular article is "processed." Some years ago we went through a canning establishment with its proprietor, who kindly showed us every detail of preparing and putting up. At last we reached the great vat, where hundreds of cans were being boiled in water.

Fig. 7.—MORTICE FOR LATCH.

"How long are these cooked here?" we asked. "Ah, that is our process!" was the reply, and that was the only secret we found about the whole establishment. Some manufacturers, instead of cooking the cans in water, use a strong brine of salt, or of chloride of calcium, either of which boils at a much higher temperature than clear water, and insures a more thorough cooking. Green corn is one of the articles about which the most frequent inquiry is made, and is one which gives the regular

Fig. 3.—CLEVIS.

canners more trouble than any other. The corn is cut from the cob, and the cans filled. In some establishments the cobs are boiled in water, and the liquor thus obtained is used to fill up the cans so that there may be no air spaces among the kernels; others use a weak syrup of sugar and salt, to fill up with. The cans are then soldered tight, leaving a vent-hole, a mere pin-hole, in the center of the cover, open, and "processed," i. e. set in a vat of water, and boiled for two hours. Each can is then taken out, set upon a bench with a sudden jar, to

shake the corn down, and allow the steam to escape; the top of the can is then pressed inwards as much as possible, the vent-hole soldered tight, and then the cans are returned to the vat, and "processed" for four hours longer. Tomatoes are canned in a similar manner, but they require less than

Fig. 9.—GATE POSTS.—(See opposite page.)

half as much boiling in the "process." It will be seen that the difficulties attending these operations in an ordinary household are such that it can seldom be advisable, especially as the products are sold at such moderate prices, to undertake them in the household. We are sometimes written to for instructions by those who would undertake canning as a business. To such we would say that it would be highly unsafe to start such a business with no other knowledge than they could get from the mere instructions of any one—even those the most experienced. It is a trade, of which, like any other trade, the general principles can be described, but success will depend upon skilled manipulation, which can only be given by those who have worked at it. Such persons should either employ a skilled foreman or superintendent.

Neatness In the Dairy.

Quality is always a measure of value; and unless perfect cleanliness is observed, the quality of butter or cheese can not be of the best. The dairyman or farmer may not perceive any difference, but the expert buyer, or the fastidious consumer, will instantly detect inferiority in flavor, and hence be slow to purchase. Means for washing or brushing

Fig. 1.—FOR CLEANING COWS.

cows are rarely seen in a stable, and still less frequently is opportunity offered for cleansing the hands of the milkers. So that in the great majority of cases impurities invariably get into the pail, are dissolved by the milk, and become absorbed by the butter. Dairy men admit the value of cleanliness and skill; but are not always aware of what constitutes proper cleanliness. As a blind man has no conception of a brilliant sunset, so some persons can not understand what perfect cleanliness and purity are. We were never more impressed with this fact than when visiting the Echo Farm Dairy at Litchfield, Ct. There the stalls were cleanly sanded, and without stain; not a loose hair was to be found upon the cows; the stable was spacious, airy, and well lighted; the cows udders were scrupulously clean; the milker's hands were carefully washed before milking, and even the conversation of the hired men was clean, foul language or noisy talk being forbidden and avoided. The most scrupulous

Fig. 2.—WATER-BOX.

cleanliness was carried out in the dairy, every utensil was pure and bright, and the dairymaid who superintended the butter-making was a pattern of feminine neatness. No one, however fastidious or exacting, could object to the product of this dairy; and there is no reason why the same methods could not be observed anywhere. A cottage can be kept as clean as a palace; and a very ordinary dairy can be made as clean as that of the Echo Farm.

We give herewith a few hints as to how this cleanly management may be practised:—All droppings should be removed out at least once a day. The litter should be short; sand, sawdust, or earth, being better than straw.

The cows should be cleaned, carded, and brushed daily, and in the spring, when the coat is falling off, they should be brushed before each milking. The stable should be well lighted, and kept white-washed and free from dust and cobwebs. Before the milking, the udders should be brushed, wiped, or washed; if washed, they should be thoroughly dried at once to avoid cracking of the teats, and clear water be used. We find a brush, or a sponge, preferable to a cloth for this purpose. A small box, arranged as in figure 1, will be found convenient. A leather strap is fastened, as shown, for a handle. The box is divided into two compartments, to hold a card, brush, sponge, and towel, and has a small pocket at each end to hold soap and some common cerate or ointment. A pail of water is taken into the stable; and to prevent fouling, a common pressed-meat can (fig. 2) is used to hold the water; the cover of which is clipped in such a manner that it may hang upon the side of the box. By this system, the labor is very slight, and a small boy or girl can go ahead of the milkers and prepare the cows. If the teats become scratched or cracked by accident, a little of the ointment should be applied to them, this being removed when the udder is cleaned preparatory to milking. There is no need to moisten a cow's teats to draw the milk easily; that is a practice to be avoided in well conducted dairies.

A Portable Sheep Pen.

Many sheep are lost from disease, caused by exposure to the hot sun of the summer months. Dysentery is a frequent complaint thus produced, which a cool airy shelter might prevent. We have found it very convenient to have even a rough shelter, made of poles and rails, and a roof of boughs and straw, in the pasture, to shade the flock from the midday sun. But this, although cheap, is often more costly in the end than a more expensive shelter. A permanent shed, built in a light manner, and mounted upon wheels, for instance, would be far more useful, and although more costly at first than the cheaper shed, would in the end pay a better profit on its cost, if it did not actually cost less at the end of 5 years than the former, with its several removals and renewals. We give herewith some suggestions of such a shed as we would build if we were in present need of one. The shed should be made with a light frame, 18 or 24 feet in length, 9 feet wide, and 6 feet high

Fig. 1.—SECTION OF SHELTER.

cleanliness was carried out in the dairy, every utensil was pure and bright, and the dairymaid who superintended the butter-making was a pattern of feminine neatness. No one, however fastidious or exacting, could object to the product of this dairy; and there is no reason why the same methods could not be observed anywhere. A cottage can be kept as clean as a palace; and a very ordinary dairy can be made as clean as that of the Echo Farm.

to the eaves. The frame would consist of two sills, two plates, four posts on each side, four cross beams, and a light roof, as shown in section, at figure 1. Braces of iron rods would serve to keep the sides from spreading, and to support the axes of the wheels. Four wheels, 2 feet in diameter, would be required. The sides should be boarded to the bottom, but the ends only half way down, as at figure 2—in which the shed is given in perspective. The sheep can then go in and out as they may feel inclined. A shed of this kind and size would accommodate 35 to 40 sheep, and need not cost over \$20, all complete. Where straw, or

Fig. 2.—PORTABLE SHEEP SHELTER.

coarse long grass is to be had, either may be used for the covering, if the frame is well made and stiffly braced. Feed-troughs should be furnished, in which bran or grain may be given. The cost of one of these sheds would be repaid each year, if only in the saving of manure, which would otherwise be dropped in the fence corners, where it is wasted, as the sheep huddle there through the day for shade. The comfort and health of the sheep would be much improved; which means profit.

Feed-Racks for Yards or Fields.

We give herewith, in response to some inquiries, some illustrations of cheap and convenient racks for feeding green crops to stock, for use in yards or

Fig. 1.—FEED-RACK FOR SOILING PURPOSES.

fields. Either complete or partial soiling is now very frequently practised, and many farmers and dairymen find it impossible to do without this help during that part of the season when pasturing fails. Early platted corn-fodder is now nearly ready for use, and in feeding this a great saving is gained by the use of racks which prevent its waste. At figure 2 is shown a common form of feed-rack; easily made, and which, if three feet square, will accommodate 4 cows without danger of quarreling. It is made of fence strips nailed together and braced as shown. Wrought nails should be used, and the same be securely clinched. A larger rack, useful for cows or sheep, is shown at figure 1. This may be made of fence strips with 4 x 4 scantling for posts, and in size 16 feet long by 4 feet wide.

Fig. 2.—CONVENIENT FEED-RACK.

BUCKWHEAT.—It does not pay to make a naked fallow, even to clear land of weeds. For to leave the soil idle for a season, is a waste of resources,

when the same useful effect can be gained in another way: any weedy, rough piece of ground may be plowed early this month, and sown to buckwheat, using a bushel of seed per acre. The weeds will thus be smothered; the rough ground be mellowed; and a fairly profitable crop be gathered. We have seeded land to timothy and clover with buckwheat sown as late as the 12th of July, and had a good catch. Otherwise the ground will be in good condition for preparing in the spring for corn, or for seeding down with barley, or alone, without any foster crop.

Straw or Fodder-Barracks.

When barn-room is short, a convenient substitute may be furnished by open barracks built in the

Fig. 1.—STRAW OR HAY-BARRACK.

fields, which also save time in hauling the crops at the busy season. Although stacking is a very cheap method of securing crops, yet in a climate of frequent heavy rains, it is rarely that a stack can be made weatherproof, unless it is so carefully thatched with straw as to cost nearly as much as a fair kind of barrack. Having recently had occasion to build several barracks upon different parts of his farm, the writer gives the following description of two of them: one, partly enclosed, to serve as a tool-house, or shelter for cattle; and an open one. The former is shown at figure 1. There are sills upon three sides, the front being open. The posts are set 16 feet apart, and are mortised into the sills. Girts

Fig. 2.—FRAME OF ROOF.

are set 7 feet above the sills, with braces, to stiffen the structure. The roof, of which figure 2 is a plan of the inside frame, slopes to each side, and is built of 2-inch boards upon 2x4 timber, braced by two sets of cross-ties, as shown. The corners

are left open, to allow the posts to pass through. Holes are made in the posts about a foot apart, into which iron pins are inserted to sustain the roof. The barrack is enclosed to the girth, giving 7 feet clear over the sills, and providing room which may be used as a stable or shed, by placing poles or timbers upon the cross-girts, to support the hay, grain, or fodder. The list of materials for this structure is as follows:

3 chestnut or oak sills,	8x8,	16 feet.
4 posts,	6x6,	16 "
8 pieces,	4x4,	16 "
3 "	hemlock,	2x4,
		16 "
280 feet roof boards,		
350 feet of boards,		

The cost of these items, with 4 one-inch iron bolts 18 inches long, and 5 lbs. of nails, can be readily figured up. The labor of putting up is worth about \$5. The whole cost will range from \$25 to \$40, according to the price of lumber.

Coops for Chickens.

Dry and clean shelter is absolutely necessary for the health of young chicks, and the mother must be confined lest she wander too far or exercise her mischievous propensity for scratching, where

scratching is not in place. A plentiful supply of good roomy coops should be on hand for use at this season; or they may be made at once, if not already prepared. The most important requisites are perfect cleanliness and freedom from dampness: if these are secured, it matters very little about the size or shape of the coops; yet convenience as to handling of the inmates, or for protecting them against sudden storms or vermin, is desirable. The floor is an important consideration; it should be movable, and elevated above the ground. A useful arrangement is shown at figure 1. There are two cross pieces of 2 x 3 timber, to which boards are nailed, leaving half the cross pieces uncovered, so that the coop resting with its edge on these may be placed entirely over the floor, in which case no water will enter from the heaviest shower. The floor is thus all inside the coop, and is raised one inch above its bottom. The coop should be 2 feet square, and may thus be made of boards 12 inches wide and 2 feet long, without waste. Some coops, which we have made of half-inch matched lining stuff, are found very light, warm and comfortable. The form is a matter of fancy, but time and labor is saved by having all of the same pattern, as then the materials for several can be cut up at once, and put together afterwards. In this way we have been able to build 10 coops in two days. The shelter-board, shown at figure 2, is hinged to the coop by a few hoops of wire, and in fine weather may be turned back or removed. At

Fig. 1.—FLOOR OF COOP.

scratching is not in place. A plentiful supply of good roomy coops should be on hand for use at this season; or they may be made at once, if not already prepared. The most important requisites are perfect cleanliness and freedom from dampness: if these are secured, it matters very little about the size or shape of the coops; yet convenience as to handling of the inmates, or for protecting them against sudden storms or vermin, is desirable. The floor is an important consideration; it should be movable, and elevated above the ground. A useful arrangement is shown at figure 1. There are two cross pieces of 2 x 3 timber, to which boards are nailed, leaving half the cross pieces uncovered, so that the coop resting with its edge on these may be placed entirely over the floor, in which case no water will enter from the heaviest shower. The floor is thus all inside the coop, and is raised one inch above its bottom. The coop should be 2 feet square, and may thus be made of boards 12 inches wide and 2 feet long, without waste. Some coops, which we have made of half-inch matched lining stuff, are found very light, warm and comfortable. In this way we have been able to build 10 coops in two days. The shelter-board, shown at figure 2, is hinged to the coop by a few hoops of wire, and in fine weather may be turned back or removed. At

Fig. 2.—COOP COMPLETED, WITH SHELTER BOARD.

figure 3 is shown a different style, which, though a little more trouble to make, when neatly finished and painted, will be found better adapted for use on lawns or conspicuous places. The front may be made of wires, laths, or turned rods of wood, and so arranged as to have a door sliding up and down. A shelter-board should be provided; and for all sorts of coops, a feeding-board should be placed in front to keep the food clean. A double coop, with an enclosed run, is shown at figure 4. This is furnished with handles, by which it may be lifted and carried from place to place; it may also be provided with movable floors, as previously described. A neat coop with young chickens are rather pretty in a well kept yard or lawn, and places valuable birds within control.

Fig. 3.—FOR THE LAWN OR YARD.

Is Cheese or Butter the Most Profitable?

The dairy-business is not, just now, in the most flourishing condition. Butter is low in price, and the question is raised if it would not be more profitable for dairymen to turn more generally to cheese-making. Butter is a perishable product; as soon as made, it begins to deteriorate, unless of that small class which is not an ordinary market-product. At the average of 30 lbs. of milk for one pound of butter, the ordinary butter-maker realizes but 2 cents for 3 lbs. of milk. On the other hand, the cheese-maker is paid from one cent to one and a quarter cents a pound for his milk, at the present prices. Besides, cheese is not a perishable article, and need not be sacrificed on a poor market, nor sold when the market is glutted. It is undeniable that the cheese-maker is better off to-day than the butter-maker, and has a large difference in his favor, both in price and convenience of handling. The cheese-maker can also churn a part of his cream, and manufacture the partly skimmed milk into a "half-skim" cheese, which, when well made, is readily marketable at a price little less than whole-milk cheese. Under present conditions the butter-maker, unless he produces a "gilt-edge" article, is

Fig. 4.—A DOUBLE COOP.

under a cloud, especially if he hails from the East. The Western dairyman has an advantage over him, and can afford to give him large odds, and then win. Western dairy goods now carry no taint with their name; they are excellent in quality, have a high reputation, and their merits sell them. They are produced more cheaply than the Eastern article, so that Western creamery butter, fresh from the churn, drives out the Eastern farm dairy product, made at larger cost on higher priced land, and with more expensive labor. The remedy for the Eastern men may be a resort to cheese-making, until butter recovers a proper relative value. Milk is selling very low in the large cities, and only near-by dairies can afford to keep in the business. Those distant from markets are being driven to the creameries for a profitable outlet for their product. This is unavoidable; and many milk-farmers and butter dairymen will follow the example. One caution is needed: This is a season of low prices and small pay for labor; it is indeed "a day of small things." If, however, quality is sacrificed, the present low level will sink yet deeper. To raise the quality of our product now is to save and secure our market; and it will be entirely safe to avoid the skim-milk cheese-manufacture, in trying to get something from both butter and cheese. Fine cheese will keep until the season is closed, and will then sell at advancing prices, because prices advance when stocks are diminishing and no cheese is making. In avoiding loss by making cheese, however, care must be taken not to invite loss by making unsalable goods.

Marking Chickens.

Poultry fanciers find it desirable to be able to identify the different broods of chicks. To do this, a method of marking is necessary. The best permanent mark is one made upon the web of the foot; and the most convenient one is a small hole, made with a punch, in the manner shown in the accompanying illustration. The punch is a sharp steel instrument, and is used by pressing it upon the web between the toes as the foot is held upon a piece of hard-wood, and giving it a twisting

THE FEET MARKED.

motion. The small piece is cut out, and the hole never closes. There is no pain or inconvenience exhibited by the chick, and it is a much more desirable mark than to clip off the toe, as is often done to the disfigurement of the bird. For this hint we are indebted to Mr. H. H. Stoddard, of Hartford, Conn.

Netting for Poultry-Yards.

The evident value and convenience of a light netting to confine poultry temporarily, or to protect gardens from the fowls, has given occasion for frequent inquiries as to where it could be purchased, and how it might be used. Heretofore it has been difficult to procure the nets, and we have been obliged, consequently, to refrain from mentioning

A FENCE OF NETTING.

their usefulness. Now, however, they can be obtained without trouble. The nets are made of twine, of different widths, from quite narrow up to 10 feet, and of any desired length. For confining poultry, the width needed will depend upon the kind of fowls. The large breeds can be kept within bounds by a net 3 feet high, while the smaller ones—Leghorns, Hamburgs, etc.—will require a width of 8 or 10 feet. To support the nets, a thin fence-wire is run through the top meshes, and this is fastened to light stakes, as shown in the illustration. The bottom of the net may be tied to the stakes by small twine. The stakes may be planted 100 feet apart if desired, if the wire is fastened at the ends to firmly set posts. The wire may be attached to the stakes by small hooks, or by pieces of tarred twine. Stronger nets are used in a similar manner for confining sheep in pastures, or when foddered upon green crops. As the wind has very little effect upon these nets, it is not necessary even for high netting to use any but light stakes; which may be planted in the same manner as is usual for tall bean-poles; that is, by making the holes with a bar, and pressing the pointed stakes into the ground by hand.

Root-Pruning Tillage

The benefits of cultivation are well known, but the explanation of the reasons for the effects are not so generally understood. Stirring of the soil that it may absorb moisture, and weed-killing, are held by the majority to be the reasons for cultivation. The killing of weeds, that they may not choke the crop, and that the right plants may have the benefit of all the fertility of the soil, is an essential feature of crop raising; but if that and the absorption of moisture were the only good results derived, then we had better sell our horse and hand-hoes, and save our labor. What good farmer has not observed that cultivation in wet weather, when the soil was thoroughly moist, was remarkable for its effect on the crop, sending it forward with wonderful rapidity? The hoeing of cabbages at such times is the most common, and very beneficial. But, according to the old view of the matter, if the theory was correct, hoeing when the soil is dry would have the best effect. Then there must be something wrong with the old idea.

Dr. Sturtevant, of Massachusetts, an able experimenter and thinker, tells us that there are two other reasons for the tillage of a growing crop, or "interculture," as he terms it. We all know that a mulch of fine straw, sawdust, or even of sand, will keep the soil moist, and often save a strawberry or other crop, or keep a newly-set plant from dry-

ing up. The action of the mulch is not to absorb moisture from the atmosphere, but rather to prevent evaporation from the soil; which evaporation means the passing off into the air of the soil moisture, and the consequent drying up of the earth. The mulch acts as a barrier to and preventative of evaporation, much as a woollen garment prevents the escape of heat from the body. As the woollen is a poor conductor of heat, so the mulch is a bad conductor of moisture.

Now the stirring of the dry soil breaks up the communication between the surface and the moist earth beneath, making in effect a *mulch* of the layer of light, dry soil; thus benefiting the crop in a drouth by preventing the escape of moisture, and *keeping* what is in the ground, rather than *absorbing* water from the air by day, or gathering the dews at night. The small amount of dew condensed and absorbed by the soil is easily realized by stirring what was dry earth the day before, on the morning after a heavy dew, and observing how little it is moistened, not deep enough to reach the roots.

So much for shallow cultivation. Let us see what Dr. Sturtevant says about deeper work. In hoeing or cultivating we must necessarily cut numerous roots. Where a vigorous growing root is cut, several new roots immediately start forth, thus multiplying the feeding power of the plant. In wet weather hoeing of cabbages, the conditions are entirely favorable for the sprouting of new roots; which doubtless explains why hoeing at that time is so beneficial. It is a not uncommon practice to dig around a tree which is spending most of its energies in producing wood and foliage; the result of which digging is to cut off a large number of its roots, stopping its growth for a time, and allowing it to mature, and changing its energies from wood and foliage to fruit production. Why not apply the same process to corn, wheat, and other crops? We do. And we have been root-pruning ever since our fathers began to handle a hoe or run a cultivator; but we didn't know it. We were waiting for Dr. Sturtevant to tell us what we were doing. Cutting the roots checks the growth for a time, and allows the plant to mature; and as soon as a root is severed, several small roots start out where but one grew before, and so many more feeders are given the plant; and since the checking of the growth turns the energies of the plant to using its already stored up nutriment in fruit production, when the new feeders begin to work they contribute directly to the same end.

A plant or an animal often develops to excess in one direction, to the detriment of other parts: as a cow to beef, with little milk; or a plant to foliage, with little fruit. As Goethe expressed it, "In order to spend on one side, nature is forced to economize on the other side." Plants grown on a too fertile soil often develop a large expanse of leaf, with but few flowers and little fruit. To turn this rampant growth in the direction of fruit and profit, we must change its course. We do this by checking the growth by "root-pruning;" thus directing the energies of the plant to seed and fruit production. This is the work of *deep* cultivation.

In cultivating corn, Dr. Sturtevant, to root-prune, runs a *deep-cutting, sharp-toothed*, cultivator, three times through the rows, beginning when the leaves reach knee-high, and *stopping* when the blooms appear, or when the tassels show themselves, it being too much for the plant to cut their roots much after that period. This deep cultivation, too, or "root-pruning," will only be found advantageous on a rich soil either naturally fertile, or made so by artificial applications, as the conditions we wish to change are only present thereon, that is, excessive leaf growth to be changed to seed production. Herein, too, lies another argument for high manuring, as the more we fertilize, the more profitable will be our cultivation.

Shallow interculture is beneficial as often as one can afford to do it, say once a week or less often. Drilling and hoeing of wheat is based on these same principles. Now, knowing *why* we cultivate, we should be able to practice "interculture" to the greater advantage of the crops, and our profit.

A Cheap Suspension Bridge.

In many places where short foot bridges may be required over small streams, they may be very cheaply constructed of fence wire, with narrow foot boards, in the manner shown in the accompanying illustrations. The supports for the wires are made by fixing a timber firmly to posts set in the ground. Five or six fence wires, No. 9 or 10 gauge, are stretched across the stream, and the ends fastened securely to the timbers. Hand wires are stretched from side to side, and fastened to

Fig. 1.—WIRE SUSPENSION BRIDGE.

posts or stakes, being carried over their tops, by which they are raised to the proper height. This is shown at figure 1. The foot boards are fastened to the wires by staples, figure 2. It is not advisable to stretch the wires too tightly, as when the tension is very great a sudden jar may snap the wire; they should be left at a quite perceptible curve. The lower outside may be connected with the upper wires, by short ones placed a few feet apart.

Fig. 2. FLOOR OF BRIDGE.

Portable Fences.

Light portable fences are often of great convenience for dividing farms, in place of permanent ones, which are generally an obstacle to clean culture, very expensive, and several of which would be required, where one portable fence might serve the same purpose. Of the great variety in use, the two here described will be found cheap, easily made, and useful. That shown at figure 1 is constructed in panels 14 feet long and 4 feet high, and made of

Fig. 1.—PANEL OF PORTABLE FENCE.

three upright bars 4 feet long and 6 inches wide. To construct a section, lay the uprights upon a smooth floor, level ground, or pieces of timber, in their proper positions; then nail to them, lengthwise, strips of common fencing stuff (6 inches wide), using wrought nails, which should be well clinched. The panels are supported by stakes on one or both sides, as may be necessary, to which they are fastened by wires or pieces of tarred cord.

Fig. 2.—PORTABLE FENCE OF PICKETS.

The bottom strip is nailed 5 inches from the ends of the uprights, so as to raise it that distance from the ground. The spaces between the boards are 5, 6, and 8 inches. Another method is shown at figure 2. Strips 14 feet long are provided, and pickets, or short pieces of waste-board, or split timber, are nailed to them, as in the cut. The panels are fastened together by the ends of the level strips, and are supported by stakes driven in the ground. A very

useful and handsome fence may be made of light poles, either split, or flattened with an ax where the uprights cross the horizontals; using wrought nails.

Sawing Timber.

A recent article, descriptive of the method of sawing timber with whip saws, has brought several enquiries for a simpler method which shall not require so much preparation. We give a plan in the illustration upon this page of the simplest manner of arranging the saw-pit. A bank of such a shape as indicated, or a pit excavated in the ground of a similar shape, will be required. A horse, or trellis, of stout timber, is constructed as shown, upon which the log is rolled, with one end remaining upon the bank, and thus sawn; being moved as may be required. When one-half is sawn through, the log is rolled on to the bank, and is swung around so as to bring the other end on to the horse, when the sawing is completed. It is better to have two horses, so that one can be moved as will be found necessary from time to time.

Effect of Fertilizers on the Grape.

That bones and similar manurial substances placed under grape-vines have a decidedly beneficial effect on the fruit, is well known. The experiments of Professor Goessmann, at the Mass. Agricultural College, and others, for the last few years have shown that certain chemical fertilizers have a marked influence in developing particular characteristics of fruit. Previous improvements in plants have been almost altogether by means of crossing varieties, by selection and cultivation: the food of the plant having been seemingly unthought of, save in a general way, beyond the accepted fact that fertility was necessary. What "fertility" means is but a vague idea to nearly every farmer or fruit grower; that it signifies the quality of fruit, as well as amount and size, is seldom realized. But such is the fact, provided the "fertility" consists in the proper constituents of plant-food. How important it is, then, that we pay more attention to the question of fertilizers, when small fruit or large fruit, fine flavor or poor flavor, pulpy fruit or fruit with the melting quality, fruit which will keep or that which will soon decay, freedom from disease or mildew—when these differences, the differences between success and failure, may be largely influenced, perhaps controlled, by the kind of food supplied at the roots. That there is an actual difference in the composition of fruit under different circumstances is shown by the following table of analyses by Dr. Goessmann, of the Concord grape, and of the purple, wild variety of the same species (*Vitis Labrusca*); the parent of the Concord:

CONCORD GRAPE. (Not Fertilized.)		Percentage of dry matter at 100°-110° Centigrade.	Percentage of grape-sugar in the juice.	Percentage of sugar in solid dry matter.	Cubic centimeters of soda solution required to neutralize the acid in 100 parts juice.
Date Gathered.	1876.				
July 17.....	8.30	0.645	7.77		
" 20.....	8.10	0.625	7.72		216
Aug. 2.....	9.94	0.933	9.44		249
" 16.....	10.88	2.000	18.33		229
" 30.....	15.53	8.62	55.33		120
Sept. 13.....	17.43	13.89	79.46		55
" 4.....	19.82	16.13	81.38		49.2
PURPLE WILD GRAPE.		Percentage of dry matter at 100°-110° Centigrade.	Percentage of grape-sugar in the juice.	Percentage of sugar in solid dry matter.	Cubic centimeters of soda solution required to neutralize the acid in 100 parts juice.
Date Gathered.	1876.				
July 19.....	9.00	0.714	7.93		204
Aug. 4.....	12.25	1.10	8.93		249
" 16.....	12.48	2.00	16.03		233
" 30.....	16.58	6.50	39.81		147.6

The figures in the last column indicate the free acids in the juice. The difference in the proportion of sugar at different dates, of fruit from the same vine, and between the wild and cultivated varieties, is quite marked; a fact very well known to those who eat Concord, and try to eat the wild ones. This variation in the amount of sugar also means a variation in acids and other constituents, and these several variations cause all the difference in flavor, texture, and in keeping quality. Yet these characteristics can all be influenced by means of fertilizers which act upon the development of the sugar of the fruit. The effects of cultivation

and fertilization on the composition of some wild varieties of grapes are shown in the following experiment. The fertilizer used in this case was composed, per acre, of 180 lbs. nitrate potash, and 450 lbs. of superphosphate, containing 12 per cent soluble phosphoric acid:

- (a) Berries of Wild White Grape, without stems, collected on the 20th of September, 1877. (Dead ripe.)
 (b) Berries of White Wild Grape, without stems, from College vineyard, treated with fertilizer No. 1. Collected 20th of September, 1877. (Dead ripe.)
 (c) Berries, without stems, of Wild Purple Grape, collected 20th of September, 1877. (Dead ripe.)
 (d) Berries, without stems, of Wild Purple Grape, treated with the above stated fertilizer. Collected 20th of September, 1877. (Dead ripe.)

	Moisture lost, at 100°-110° Centigrade.	Percentage of dry matter at 100°-110° Centigrade.	Percentage of grape-sugar in the juice.	Percentage of sugar in solid dry matter.	Cubic centimeters of soda solution required to neutralize the acid in 100 parts juice.
(a)	79.98	20.02	10	49.95	130
(b)	78.35	21.65	14.29	65	65
(c)	73.31	16.69	8.22	49.25	104
(d)	80.45	19.55	13.67	60.92	121.6

These analyses show very decidedly the influence of mere cultivation on wild varieties, making a difference of nearly 20 per cent of sugar. Further investigations in this direction are in progress.

It has been found, by Dr. Jahes Fisher, an unusually successful grape-grower, that animal ma-

SAWING TIMBER—ANOTHER METHOD.

nures make strong vines, but not much fruit, and tend to induce rot and mildew; while potash and superphosphate had quite the opposite effect, producing a large amount of fruit, of superior quality. Mr. Anger, the State Pomologist of Connecticut, is trying similar experiments, as well as several others, in conjunction with Dr. Goessmann, and with remarkably like results in each case.

Increased Rainfall in the West.

As might have been anticipated, the rainfall in the far Western States, formerly hardly adequate for the purposes of cultivation, has considerably increased since the occupation of the country, and the cultivation of the prairies. Heretofore every condition has been unfavorable to the retention of the water in the soil. The surface, beaten hard, and covered with an impenetrable sod, could not absorb the rain water, which soon found its way into the water courses and streams, leaving little

moisture in the soil to temper the aridity of the atmosphere. The winds were dry and thirsty, and sucked up the water left in pools and swales with great rapidity. But as soon as the tough sod has been plowed, and the soil been mellowed and made absorbent, the rain soaks into the ground instead of flowing off, and percolating through the subsoil, supplies springs, which break out in low spots and furnish water for new rills and brooks. The atmosphere is no longer parched, but becomes moist, and its former extreme variations of temperature do not occur. The climate changes, and the moisture of the air, and the consequent rainfall, are increased. A new circulation is established, and the storms and showers are those of a temperate instead of a torrid zone. Facts have shown that these conclusions are correct, and the observations taken in many places near the 100th meridian, and eastward to the Missouri River, indicate a greatly increased rainfall, the increase amounting in many cases to several inches a year. Farmers no longer fear disastrous drouths, and there are few localities, where their business is safer, than in the locality referred to.

Irrigation in Colorado.

A practically rainless district, the agriculture of Colorado is necessarily carried on by irrigation. This has been hitherto a little understood art in the United States, but recently it has been practised with such success, that it is rapidly extending through the arid parts of the country. The literature of irrigation too, has made a beginning with us and its principles set forth for those who would practice it.* By and by we shall know more through the experience of irrigators, and the skill of hydraulic engineers; and it will become widely used as an indispensable means of cultivation itself, as well as an accessory to ordinary methods. The example of Colorado is very instructive and encouraging. This now populous and prosperous State, was settled by a handful of enthusiastic, but shrewd men, who took their fortunes as it were in their hands and launched upon an unknown enterprise. Had they known the history of this art of irrigation, and the extent to which it has been and is now used in other countries, there would have been less doubt about their venture. As it is they have made a grand success of what they did not know could hardly have failed with proper methods, but the credit is none the less for them. At first it was doubted if Colorado could sustain its farmers. Now it not only sustains a large population engaged in varied industries, but exports much of its products eastward. As the capacity of the streams is better understood, and as economical methods of using the water are learned, the breadth of land under irrigation is rapidly widening. Nearly a million acres of land is expected to be brought under cultivation the coming season, and new canals are begun and proposed. Hitherto the prices of produce have valued high, which has tended to encourage the enterprise. As production increases, prices are falling, but this will act in favor of the development of the mining, manufacturing, and stock interests, which in turn will enlarge the outlet for farm produce, and stimulate agriculture.

TOBACCO.—The late unpleasantness experienced by tobacco growers, has given place to a more satisfactory condition of things. The last crop of "seed-leaf" has been of unusually good quality, which has had the effect of stimulating buyers as well as prices. Dealers are feeling elated at their position, and are looking for an early resumption of activity in business. This warrants an easier feeling amongst producers; and the prospects are fair for a gradual return to the cultivation of this crop. While tobacco is not exactly a staple farm crop, yet there are numerous cases in which a farmer, who has prepared himself at a large outlay to grow it, may reasonably manage his farming operations so as to look for his money income from this source, in preference to any other.

* "Irrigation for the Farm, Garden, and Orchard," published by the Orange Judd Co., New York, price, \$1.50.

The Canada Violet (*Viola Canadensis*).

The few of our native species of Violet which have any perfume, possess it in so slight a degree, that we cannot commend any of them for cultivation for this quality alone. If we look for perfume, we must take some variety of the European Violet (*Viola odorata*), and accept our own for the beauty of their flowers only. In former volumes we have figured the beautiful Birds-foot Violet (*Viola pedata*), beautiful in its ordinary form, and especially so in its white and two-colored varieties; these plants, notwithstanding their lack of odor, are, on account of the abundance, large size, and long duration of

stem or two, and all we can hope to do, is to show the shape of the leaves and flowers, and give an idea of the details of the plant. It forms a dense mass of such stems as these, from a foot to two feet high, and produces a great profusion of flowers, which last a long time. The flowers are mostly white on the inside, the side-petals bearded, and the upper ones tinged with purple on the outer surface. Some variations from the usual form have been noticed, and it is very likely that careful observers will find that this is quite as much disposed to sport, as are the other species. Our California friends will find in their rocky woods, a species which is much like the Canada Violet. Indeed, when we first came

those who do not know *Kerria*, one in making his selection passes this by, and the nurseryman concludes that there is no demand for good things. It is a fact, and we may as well accept it, that people in general do not take to botanical names. However unreasonable this may be, and however we may show that some botanical names, such as *Magnolia*, *Geranium*, and others, are in common use, the fact remains that if we would popularize a plant, we must give it—unless its botanical name happens to be one like *Coleus*, which every one can remember—a name that will take. For this reason, in calling attention to a useful and showy Japanese shrub, *Rhodotypos*, we have been at some pains

CANADA VIOLET—(*Viola Canadensis*.)

their flowers, in much esteem among European gardeners. Some of the forms of our commonest Blue, or Hooded Violet (*V. cucullata*), some of which have pure white, and others variously blotched flowers, are finding their way into cultivation. During the past season we have had several forms of this sent for a name, showing that it has obtained a foothold in various gardens. The two native violets we have named, the Birds-foot, and Hooded (the names referring to the form of the leaf), belong to the section of stemless violets; i. e., their leaves and flower-stalks all come directly out of the ground, having their origin from a subterranean stem. Besides these, we have a set of native violets with branching stems, and of these perhaps the most conspicuous is that, which Linnaeus called *Viola Canadensis*, the Canada Violet, but which is by no means confined to Canada, as it is found in all the Northern States, and southward along the Alleghany Mountains. It is a native species more frequently found in cultivation in Europe than with us, yet we are sure that any one who saw it in masses, as it grew in our rock-work this spring, would admit that it was well worthy of cultivation. In giving an engraving, we are confined to a single

upon it in that rich botanical region, around the mines of New Almaden, we hailed it as our old New England friend, but a closer inspection showed it to be the Western representative of our species, the Eyed-Violet (*Viola ocellata*) of Torrey and Gray, so called because each of the side-petals has a little purple spot or "eye" near its base. A very neat species it is, and we advise the many lovers of flowers on the Pacific coast to introduce it into their gardens, which they can readily do, when the dry summer puts this, as it does their other lovely spring flowers to rest, and the roots are dormant.

New Japanese Shrubs—The Jamabuki.

Japan has greatly enriched our collections of hardy shrubs and herbaceous plants, and while a number of the shrubs from that country are well known and popular, we find that others, equally meritorious, are seldom seen in cultivation. If one takes up a catalogue, and finds "*Rhodotypos kerrioides*, a fine shrub from Japan, with the habit of *Kerria*, but large white flowers," as there is nothing in the announcement to attract the attention of

JAMABUKI—(*Rhodotypos kerrioides*.)

to hunt up its native name, and give our readers the choice between the botanical *Rhodotypos*, meaning "rose-form," and the native Japanese name *Jamabuki*. There is but one species of *Rhodotypos* thus far known, and it has been named *kerrioides*, from the marked resemblance of the foliage of the shrub to that of *Kerria Japonica*, the old "Japan Globe Flower" of our gardens, which makes itself almost a weed, and which is still known in some catalogues by the incorrect name of *Corchorus*. The "*Jamabuki*," or *Rhodotypos*, is a perfectly hardy shrub, flowering in April, its foliage being so much like that of *Kerria*, as to warrant its name; but the flowers, instead of the deep yellow of *Kerria*, and their flimsy texture, are of the purest white, and much larger and firmer. The engraving gives flowers and leaves of the natural size. The plant belongs to the Rose Family, and, unlike most of the showy members of that, it has but four petals, the usual number being five. The fruit consists of (usually) four little stone fruits, like the grains of a blackberry, and according to Siebold and Zuccarini, who first described it, become of a brilliant black color, and remain so until the middle of winter. We have had the plant in cultivation for sev-

eral years, and find it one of those easy-growing things that has every element of popularity. It is not particular about soils, does not get so rampant as to need much sheeking, forms a shapely bush, which in early spring shows an abundance of pure white flowers, which last a reasonable time. It is equally deserving of a place in the shrubbery with the Weigelas, which are now deservedly popular.

The Oleander Poisonous.

The different varieties of the Oleander (*Nerium Oleander*), so popular as house plants in cool climates, are in warm countries often cultivated as ornamental trees, and used as hedge plants. The tree, in a suitable climate, will reach the height of 20 to 30 feet, and forms a most beautiful object, both in its leaves and flowers. But with all its attractiveness, it has the misfortune to be highly poisonous, a quality not so likely to be manifested when grown as a house plant, but one which becomes of serious importance when it is in common cultivation in the open grounds. Some months ago, one of our correspondents in Bermuda, where Oleander hedges are very common, wrote to ask if the tree could poison the herbage around it, as he had found animals that grazed near the Oleander hedge were frequently made seriously ill—a trouble which might be readily caused by a few fallen leaves. Later accounts come from another British colony, New South Wales, of the death of six cows at Sydney; the animals were fed upon grass recently cut from a lawn on which the Oleander grew, and its leaves became mingled with the fodder.

It is quite likely that the poisonous principle is more active in climates which will allow the plant to grow continuously in the open air; still, while we do not remember to have heard any casualty from house plants, it is well to know of the danger and be on guard against it. St. Louis, Mo., may almost be called the City of Oleanders; such is their abundance, that it would seem that every house has one or more bushes, and the markets are gay with them. We should expect accidents here, if any where, from the plant. A case is recorded in Europe, in which fatal results followed eating meat in which a skewer of Oleander wood had been used.

Dwarf Pear Culture.

We were recently in the pear-orchard of one of our most distinguished pomologists, who had put out some eight hundred trees of all the well-tested varieties, as well as those that promised well. The ground had been most thoroughly prepared, cleared of stones, trenched, and enriched with stable and other manures. A large portion of the trees were dwarfs, cultivated in rows, with ample space between for vegetables. The ground was annually manured, and kept in the highest cultivation. Great pains were taken to train the limbs of the dwarfs very low, to shorten in the annual growth, and by thinning the fruit to restrict the bearing to the production of limited crops of the very finest specimens. It must be said in justice to the experiment, which extended over some twenty years, that while the proprietor lived, and gave his personal attention to the dwarfs, the most of the varieties flourished and gave fair crops, though they could hardly be called remunerative, when compared with the products of his standard trees. Since the death of the proprietor, which occurred some two years ago, they have missed his supervision and the care also of a competent gardener. The rows of dwarfs are sadly thinned, many of them having been cut down as unprofitable, and the spaces between are covered with a wonderful growth of clover. In our own garden we have three dwarf-pears—two Bartlett's and a Muskingum, the planting of a former occupant. They bear a limited quantity of good fruit every season, but they do not compare favorably with the yield of standards planted at the same time, and sharing the same treatment. We have three trees contiguous in the same row, a dwarf Bartlett, a dwarf Muskingum, and a standard Viear of Winkfield between the two.

From the Viear last fall we gathered a barrel of pears, and not to exceed a half bushel from either of the others. This is about the average yield of the dwarfs, and less than the average of the standard.

For market purposes we doubt if the dwarfs can be made to pay. They are desirable in small gardens, where one is anxious to eat fruit of his own growing at the earliest date after planting. The desirable varieties that do well upon the quince are quite limited. Belle Luerative, Duchesse d'Angouleme, and Louise Bonne de Jersey, are among the best in most soils. Then come St. Michael, Lawrence, Comice, Beurre Diel, Beurre Bose, and Doyenne d'Ete, which succeed fairly with generous culture. The dwarfs require a richer soil and more attention than standards. Some varieties yield finer specimens upon quince than upon the pear-stock. The dwarfs are properly regarded as the pets of small gardens, on which amateurs in narrow quarters may bestow their husbandry. CONNECTICUT.

[Our correspondent's notions as to the market-value of dwarf pear trees—that with few exceptions, and these annually growing fewer, they are not advisable, are well expressed by an old Dutch market-gardener in our neighborhood. He says: "You plant a dwarf pear tree, and you can go for your crop with a basket; plant a standard, and you must take a wheelbarrow and a barrel.—ED.]

The Thick-leaved Elm.

In January last, we gave an engraving of a twig of the Thick-leaved Elm (*Ulmus crassifolia*), with notes from our own observations of the tree, and asked for further information concerning its value from those living in its native localities. We are favored by a letter from E. H. Smith, M. D., of Victoria Co., Tex., from which we abstract the following: "This tree is abundant on the Colorado [of Texas, Ed.] and on all the streams west, to and including the Rio Grande, and also on their tributaries. In our rich river valleys, its average diameter is 20 inches, while on high dividing ridges, and at the head of small streams, its diameter ranges from two to ten inches. This difference in size is accounted for by its capacity for enduring extremes of dryness and moisture. The tree makes no approach to an evergreen, its leaves being dropped on the first advent of cold. For a dense shade, where it is not crowded by other trees, it is unequalled, and I think it would prove hardy in almost all parts of the United States. The wood makes a good fuel, and it is often made into rails and shingles; rails of this wood last only about five or six years, but I have known a roof shingled with this Elm to be good for more than ten years." Dr. Smith will please accept our thanks for his note.

Fighting the Canker-worm too Late.

A correspondent writes: "The canker-worms have made their appearance in great numbers in Eastern New England, even upon trees that were tarred during March and April. This does not prove that the application of tar is not a successful remedy. The open winter, which admitted of plowing in January in some places, also favored the ascent of the moths. In severe winters, there is probably no ascent of the moths until spring. Harris says: 'It was formerly supposed that the canker-worm moths came out of the ground only in the spring. It is now known that many of them rise in the autumn, and in the early part of winter. In mild and open winters, I have seen them in every month from October to March. They begin to make their appearance after the first hard frosts in the autumn, usually toward the end of October, and they continue to come forth, in greater or smaller numbers, according to the mildness or severity of the weather, after the frosts have begun. Their general time of rising is in the spring, beginning about the middle of March in the latitude of Massachusetts, and they continue to come forth for about three weeks.'

"No farmer who beholds the melancholy aspect of his orchard this summer, riddled by the canker-

worm, should infer that the case is hopeless. The tar should be applied always on paper or cloth—never directly on the bark—as early as the 1st of November, and it should be renewed daily as long as the insects continue to rise. This can be known by the capture of the female moths in the tar. While the ground remains frozen upon the surface, there can be no danger from the insects, and, of course, no need of the application. In the latitude of New York City, there will not be more than 60 days that the tar will be needed. This remedy is effectual, and it is only expensive in labor."

Notes from the Pines.

Those who have been so enthusiastic over the early spring, had abundant reason to change their note about May 12th. I say about that date, as a wide-spread frost from the far West to the far East occurred, either two or three days before or after that time. Many, trusting to the early promise, and forgetting the lessons of former very early springs, had prepared themselves for disappointment, and as I went to and from the city in the cars, the losses in Tomatoes, Lima Beans, Corn, and other crops, seemed to form the chief topic of conversation. Our chief loss was

Among the Grape-Vines.

These we could not well retard if we would, and the succulent shoots had pushed just far enough to expose the whole "set" of buds for the crop—and a most promising set it was—to the action of the frost. The vineyard presented a sorry sight when a few succeeding warm days had quite dried the shoots and leaves that the frost had killed. Yet, on going over the vines, I find probably a fourth of the clusters of buds unharmed, and it is likely, if we can manage the rose-bugs, that we shall still have some grapes. In many cases the shoots were killed back, but not quite far enough to reach the clusters; in these cases I allow the uppermost sound "lateral" to grow, and that will furnish enough foliage to perfect the fruit. Still the evil was not without its compensations. Some vines had from one cause and another got out of training, and these were cut back

For a New Start,

throwing the whole energies of a vine several years old into growing two arms for another year. Another benefit. I had working with me a pupil who had been studying vine structure and growth, and as in this case each vine had to be treated according to its present condition, and what was expected of it in future, he volunteered the opinion that "an hour of this experience is worth more than all the books."... There is much talk of the

Injury to Strawberries

by the frost, but so far as ours go, and some of them are on rather low land, where the frost was most severe, I find but little damage. The Strawberry is a fairly hardy plant, and while no doubt those flowers that happened to be in full bloom just at that time were blighted, and will fail to perfect fruit, enough will escape to give a good crop. The fact that the flowers of the Strawberry come on in succession, and but a few of the whole number are in full flower at once, has no doubt saved them. As to Strawberries—last spring Messrs. E. & J. C. Williams, of Montclair, N. J., sent me a dozen plants of their new variety,

The "Duncan" Strawberry.

These were put out where they might multiply, but being at the end of a row grown for fruit, from which the runners were kept off, the man who was to cut the runners from the old plants, also kept the Duncans clear of them, and I had this spring only the original dozen plants. What they would have done had it not been for the frost, I can not say, but while they did not bear many berries, the few they did give were so far ahead of any others that I am almost afraid to write "two weeks." Still it is a fact that in this spring of 1878 the "Duncan" gave us ripe fruit two weeks before any other of some 20 or 30 varieties, but not much of it. See here, Messrs. Williams, if you quote this—quote it all—"excessively early, but a very small crop in an

unusual season." Year before last, the Messrs. Williams brought me some quarts of the fruit, as sent to market from the original bed. I then said it was of fair quality—much better than the Wilson. I now say, from the fruit, ripened on my own vines, that it is more than fair, it is *good*. Those not familiar with fruit nomenclature should understand that fruits are classed as "good, very good, and best," and few be they that are placed in the last category. To avoid misunderstanding, I will say that I do not put the Duncan down as a poor bearer, for it must have been in its fullest flower just at the time of the heavy frost. I speak of it as it behaved *this season*, with the condition of unintended cutting of the runners already mentioned. What a difference there is in tastes. In such a multitude of shrubs as I have, there are a few that are prime favorites, and among these is

The Virginian Fringe-Tree,

Chionanthus Virginica.—I use the prefix "Virginian" because some nurserymen will persist in calling the "Smoke-tree," *Rhus Cotinus*, the "Purple Fringe."—The true Fringe-tree, when in full bloom, richly merits the name; it is a cloud of white fringe-like flowers, each individual flower having four long narrow petals, looking as if cut from the thinnest and whitest paper. A gentleman who lives a few miles away, was here a few days ago, and in showing him about I exercised proper tact in reserving the best things for the last. He admired the (so-called) Scarlet Horse-Chestnut, and went into ecstasies over the Weeping Hemlock (and well he might) and other evergreens, just in the glory of their new growth. When at last I brought him to what had been reserved as a *bonne bouche*, as the one choice thing I had to offer, and expected the appreciation that everything else had received, he quietly remarked, "Do you call that handsome?"—It was not so to him, and that is all there is to be said about it.... I have my hobbies—what gardener hasn't?—the Fringe-tree is one of them, and another is

The Ramanas Rose of Japan,

which was figured in the *American Agriculturist* for Sept., 1875. My plants, the red and white, are from the original stock sent out years ago by Thomas Hogg, Esq., and are now great strong bushes; not only "things of beauty," but "a joy forever" of the whole season round. In the first place the foliage is a "joy" of itself. Its dark-green substantial character seems to defy all insect attacks, and though the plants are in a bed with common roses, which are favored by the slug and every other rose enemy, these are always intact. Then the flowers, four inches or more across, are produced in the greatest and long-continued profusion. To be sure they are *single*, but their wonderful fragrance, and their abundance, will compensate for this, even with those who can see no beauty in other single roses. Then after this "Ramanas Rose" has bloomed long after other roses have ceased, it hangs out its wealth of great crimson fruit, as big as crab-apples, and is almost as showy as when in flower. We have a plant of this rose said to be double; it has not yet flowered, but it must not give up any other good quality in making double flowers, to allow it to take the place of the excellent single one.... Speaking of roses reminds me that Mr. Peter Henderson sent me not long ago a specimen of a rose having

Two Distinct Colors on One Plant.

The specimen was not more than six inches high, yet it had two flowers upon it, one a pure white, and the other a deep blush—not such changes as might be due to the age of the flowers, as sometimes happens, but distinct from the start. This is one of those not very rare examples of

"Bud Variation,"

a term happily chosen by Darwin, that now and then occur in our cultivated flowers, and of which the acute florist takes advantage to perpetuate new varieties. Several of our popular roses have originated in this way—notably the two "Sprunts" in this country. A remarkable instance of "Bud variation" occurred in Mr. Henderson's own experience. He sold to a neighbor starting in floriculture

a lot of Bouvardias, all from the same stock, when this neighbor's (Mr. Vreeland's) Bouvardias came to bloom, there was one so unlike the rest, and so distinct and valuable, that it has been propagated as *Bouvardia Vreelandii*. None of the remainder of Mr. H.'s large stock showed the same variation.

The Abuse of Pain.

The little nerves of feeling which run through all parts of the human body carry to the brain intelligence of disaster and of pleasure. The evil messages they bring are called pains. A pain admonishes us that some injury is done to a part of the body—a finger jammed, a toe cut, an arm burned—or that some part is overworked or is wearied out, and must have rest. The nerves but do their duty, when they report faithfully these things, and our duty is to do the best we can to repair the mischief which caused the nerves to report in the way of pain. But many persons are annoyed by these evil messages, and only seek to silence the messenger. The immediate call is for something to "still the pain." Fortunately, the means employed are sometimes such as correct the evil at once, and so put an end to the trouble reported by the nerves. Especially is this the case when cool water is applied to cuts and burns—the relief and the cure begin and go on simultaneously. The same result is usually attained when hot water applications (or fomentations) are made to bruises and sharp pains of various kinds. Pain, which results from overdoing of any kind, is most reasonably "stilled" by rest—general rest of the whole body, and especial rest of the overworked part. Anything that tends to equalize the circulation of the blood, or to make all parts of the body comfortably warm, and no warmer, helps to set the nerves at rest, or to stop pain and disease. Not long ago I saw a man who was suffering with a violent headache (a neuralgic general toothache) furiously kicking, first with one foot, and then with the other, working to get the blood from his head to his heels, because he had found that the most effectual way to cure his headache. Cool applications to the head, and hot ones about the feet and legs might serve the same purpose.

Morphine Drinking.

But I set out to speak of a habit which prevails to an alarming extent among women—the use of morphine, to quiet pain of one kind or another. I can easily imagine that the habit may grow from ignorance of danger. A fearful pain is lulled by seemingly simple means—an opiate in the shape of morphine. The suffering one rests easy, and pitying friends may believe that morphine was just the thing needed. But has the opiate cured the disease which caused the pain? Not a bit of it. It has only beaten down and silenced the faithful monitor, the nerves which, in the shape of pain, told of injury and begged that help be given to the injured part. It is true that Nature, and not medicine, performs the cure, and that the blessed work of restoration to health usually goes on best during sleep, but it should be natural sleep. This will usually come of itself if you put the body into suitable condition—the pores of the skin open, by bathing or rubbing judiciously, the bowels properly relieved, the stomach nourished by simple food, easy of digestion, the lungs supplied with pure air, and cleanliness and quiet all about the patient. But when you give or take the dose of morphine, you make a deadly attack upon the nervous system, and leave the evil condition of things in the body to go on. The dose must soon be repeated, and as the habit of resorting to an anodyne strengthens, the dose must gradually increase, in order to produce the desired effect. Such a course finally breaks down the nervous system, and leaves the one who resorts to it a hopeless wreck—the worst kind of a drunkard.

Mothers, it is believed that those who are most

likely to become the victims of morphine are women who, as children, were lulled with soothing-syrup (and let it always be remembered that this syrup derives its "soothing" power from the morphine it contains), or dosed with paregoric or the more potent laudanum. They never learn to bear pain heroically. They grow up inclined to self-indulgence, and if hard work and sickness overtakes them, they fall an easy prey to morphine. Do you know that a person who becomes addicted to morphine cannot be decent without it? It is said that a morphine drunkard can never be trusted to tell the truth. She becomes at last so unbearable in disposition, when not under the influence of her medicine, that her friends make every effort to gratify her morbid appetite. All this that I have said applies equally to the use of opium, morphine being but another form of opium. Neither should be used, except in some emergency, when given by a skillful physician.

Care of Children's Eyes.

It is no uncommon thing now to see, or hear of, mere children using eye-glasses, because of some defect of sight. Myopia (or near-sightedness) is the most common defect, and it is said to be manifestly increasing among school-children, in other countries as well as in our own. The eyes of studious children are especially liable to suffer. Reading tires weak eyes, and eyes grow weak or diseased from too steady application to books. There are many disadvantages connected with learning the alphabet in very early childhood, and danger to the sight may be reckoned among them. The eyes of children, like all their other organs and faculties, are adapted to the study of natural objects, or the phenomena of the world into which they have lately come. This study is play to them, and tends to a healthy development of both mind and body. Their introduction to the fine long lines of little black letters in print should not come too early, or too rapidly—not until a love for nature and a faculty for observation have been so cultivated that reading will not be immoderately attractive. Then they must learn to read and study in a proper light, one that shines upon the book or paper, and not directly upon the eyes. A hanging lamp is much to be desired, and those who read in the evening can sit so that the light comes down upon the page from behind them. In gathering about the evening lamp upon the table, those who read should sit so that the light shines upon the book or paper from over the shoulder—and the left shoulder if practicable. The eyes suffer severe strain from reading when lying down. One who is too tired to sit up, is too tired to read. When the body is enfeebled by disease, the eyes are weak sympathetically, and should not be allowed close application. Reading in railway cars, or in any place where it is impossible to keep a steady focus for the sight, causes strain and injury to the eyes. Children should be taught to avoid all these injurious practices.

Most of the youthful cases of near-sightedness within my knowledge are those who began to learn piano-playing when quite young, and it seems to me that the fixing of the sight upon the notes, while the energies are at the same time bent upon the schooling of the fingers, has a peculiar tendency to develop near-sightedness. Ought not a child's music lessons to be made very short, and the hours of practice few and of brief duration? I think so, not only for the sake of the eyes, but also for the sake of the spinal column and the nervous system.

Starch for Fine Muslins.

A solution of Gum Arabic in water makes a nice starch for lawns and thin muslins, giving them a new appearance. Dilute the dissolved Gum until you find by experiment that you have it just right. It takes but a minute to rub a cloth in it, slightly dry and iron it, to test the strength of the gum water. I am unable to give exact proportions. Lawns renewed in this way, after washing, not only look as though just made up, but retain their good appearance wonderfully well.

To Keep Lemons Fresh.

I have found that lemons may be kept fresh for many weeks if put into cold water. Some use sour milk instead, changing the lemons from one pan to another as the milk grows old. This involves

more trouble and risk, and I hardly think it can be any improvement upon the method with water. Still another way (recommended by one in whose judgment I have confidence), is to bury them in the sugar-barrel. We don't all have barrels of

Fig. 1.—A V-SHAPED LEACH.

sugar, but I suspect that salt would answer the same purpose—anything that prevents the evaporation of the fluid of the fruit and keeps it cool. I wonder whether the lemons would not impart some flavor to the sugar in which they were buried. Of course this would not be desirable. My friend said nothing about that.—[This advice, no doubt, refers to brown, or other unrefined sugar, and the following of it can hardly fail to flavor the sugar. We were once told by a sea-captain that he kept lemons for a long time by placing them in a jar, or keg, and covering them with molasses. The chief object is exclusion of air, which the molasses would do most effectively.—Ed.]

In Making Lemonade,

we usually pare off the yellow peel, unless the lemonade is to be used immediately, because the peel, by standing with the sugar, imparts a bitter taste to the drink. Some roll the lemons before they are peeled and sliced, to break the cells and set free the juices. Others slice the lemons upon the sugar, in the proportion of one lemon to two large spoonfuls of sugar, mashing the slices with the sugar and leaving it just covered with water for 10 or 15 minutes before filling up with water.

Lemon Flavoring

may be prepared at home in two ways. 1. Save the peelings of lemons used for lemonade or other purposes, when the peel is not all required by the recipe. With a sharp, thin knife, cut off the yellow part, and dry it quickly without scorching. Keep it in a dry place, and when needed, grind to a fine powder before using. 2. To two ounces of the thin yellow lemon rind, add one pint of good Alcohol, improving it if you choose with a few drops of Oil of Lemon. In a few days it is ready.

Lemon Pudding Sauce.

One lemon—the juice and half of the grated peel. One heaping tea-cup of sugar, one-third of a cup of butter, one egg. Beat well together the butter, sugar, and egg, then the lemon (and a little nutmeg if you choose). After a thorough beating together, add slowly half a tea-cup of boiling water, stirring it constantly for a few minutes, keeping it as hot as possible without boiling it.

Baked Rhubarb.

A delicious sauce is made by baking the sliced stalks of rhubarb with sugar. Cut the slices an inch thick, and bake in a deep earthen pudding-dish, after mixing a tea-cupful of sugar to a pint of sliced rhubarb. This can be preserved by canning while boiling hot, the same as fruit.

Rhubarb and Orange Marmalade.

Take one dozen oranges; pare off the yellow peel, discarding the thick white rind and seeds. Cut the peel into fine bits, and put it with the sliced pulp. Add two quarts of sliced rhubarb, and three pounds of loaf or granulated sugar. Boil the whole slowly until it is quite thick. Turn into enps and cover, when cool, with paper varnished over with white of egg, pasted to the cup.

Strawberry Shortcake.

Any good biscuit mixture will do for the shortcake. It is common to make it with sour cream, or sour milk (and soda, of course), with more or less butter, as the milk is more or less creamy. Roll out to form two thin sheets, placing one above

the other. When done and still warm, the two sheets of the cake easily separate without cutting. Butter each half on the soft side, and cover thickly with sweetened strawberries. Place one sheet above the other, strawberries uppermost.

Canned Strawberries.

It is an excellent way to sprinkle sugar over the hulled berries, and let them stand two or three hours. Say a heaping tablespoonful to a quart of fruit. Pour off the juice into the preserving kettle, and add sufficient sugar to make a good syrup. When hot, put in enough berries to fill one can, and allow them to boil about two minutes. Dip out the berries, boiling hot, into the bottle, and pour in enough of the boiling syrup to fill the can. Seal immediately. Put a fresh lot of berries with a little more sugar into the remaining syrup, and treat in the same way. If syrup remains when all the berries are canned, it makes excellent jelly. If the berries stand too long in the sugar, it injures their color and leaves them less firm.

Leaches, Lye, and Soap.

In the older States, before the general use of coal as fuel, a leach was an important household appliance; the ashes from the wood burned during the winter were carefully saved, and in spring, these, with the careful housewife's savings of soap-fat, were put to use in the annual soap-making. As wood as a fuel went out of use, good, honest home-made soft-soap also disappeared. Still there are localities where wood is yet the fuel, and though these are much less than formerly, they are sufficient to bring us a number of inquiries about lye and soap-making. The value of ashes depends upon the kind of wood used, the soft woods yielding ashes very poor in potash, which is the important constituent so far as soap-making is concerned. Where soap is to be made from ashes, the first step is to extract their soluble parts, to get a solution of them in water, known as *lye*. To do this, the ashes are placed in some receptacle, called a *leach*, in which water can gradually trickle through them, and come out below as a strong solution or lye.

Fig. 2.—USING A HOGSHEAD AS A LEACH.

Our correspondent, L. D. Snook, of Yates Co., N. Y., sends us drawings of two common forms of leaches. Figure 1 represents the old-fashioned V-shaped leach, sufficiently well to show its structure. There is a frame of 2 x 3-inch scantling, about a foot from the top, which is stayed by side pieces; the bottom is a log, in which a gutter is dug, to convey the lye to a pail, or other receptacle, placed at its lower end. The manner in which the leach is supported, and the arrangements of its side-boards, is sufficiently shown in the engraving. Sometimes an old sugar or molasses hogshead, obtainable cheaply at "the store," is used as a leach. The hogshead, first having half-inch holes bored in its lower staves and ends, is set up, as shown in figure 2, upon a grooved plank, which will convey the lye to a vessel placed to receive it. This is kept in proper position by a frame, or by braces at the sides, as shown in figure 2.

To "Set the Leach,"

as putting it in operation is called. The old method was to put in the bottom some bricks or stones, then some brush, and over this a layer of straw, and then put in the ashes. This will answer, if no

better method can be followed, but it is much easier and better to place on the bottom of the leach, of whatever kind, a piece of old blanket, or old carpet. This will accomplish the purpose for which the straw, etc., are used—i. e., to prevent the ashes from clogging up the holes, and allow the lye to flow out. Ashes moisten slowly, and in filling the leach, it is better to put in a small quantity at a time, moistening each layer as it is put in, and compacting it with a pounder of some kind. If the ashes are thus moistened all through, the leach will work more evenly than when filled dry. It is customary to make in the top of the ashes a cavity large enough to hold a pailful or two of water, and replenish the water as it soaks away. The more slowly the water percolates among the ashes, the stronger the lye will be. It is a common practice to put lime in the leach, six or eight quarts of quick lime being placed on the first layer of ashes. This makes the lye much stronger, the lime converting the carbonate of potash, as it exists in the ashes, in part into caustic potash.

Making Soap with Lye.

There are some facts about soap-making not generally understood, and are here given in brief. The alkali in lye from wood-ashes is always *potash*. Potash will not, with any fat whatever, form a *hard* soap. All hard soaps contain *soda*, instead of potash. All the recipes that are sold for making hard soap from potash, or from lye, require the use of salt. The salt decomposes the potash soap, its soda taking the place of the potash and forming a hard soap with the fat, while the potash, having formed a new combination, remains in the liquid at the bottom of the kettle. From lye alone, then, only soft soap can be expected, and this, when well made, is very useful for ordinary domestic purposes, and vastly better than the soft soap sold all over the country, which is merely common hard soap, thinned to a sort of jelly with water, and is a most expensive article to purchase. While almost every farmer's wife, who makes soap from lye, can do it satisfactorily, and have the soap "come" every time, she will find it difficult to give a precise rule, so much depends upon practice and judgment, or "gumption." In a general way she takes the strongest of the lye, and boils it with the rough grease, pours this into the soap barrel, and then adds the weaker lye as it runs from the leach. The usual result is a barrel of good strong soap, made without much reference to rules or proportions. So far as we can come at a rule, for soap with lye, an experienced soap-maker says: "Have the lye strong enough to float a potato. Take 12 pounds of clean grease, previously tried out, and add to it four gallons of lye, and boil together over a slow fire; put this into the soap barrel, and add more and weaker lye, to make a barrel of soap, frequently stirring."—It will be seen that this is far from definite, and we shall be very glad if some one will give a more precise rule. In making soft soap from potash, the usual rule for a barrel of soap, is 12 lbs. of potash to 14 lbs. of grease. Dissolve the potash in about two pailfuls of hot water, poured on it over night. The potash dissolves quite slowly, especially if in compact lumps. Have the grease, previously rendered, in a barrel, and pour on it the potash liquor, stirring well. If some of the potash, as will probably be the case, remains undissolved, pour on more hot water, and the next day add this to the barrel, and continue doing so, stirring thoroughly, until the potash is all dissolved. Then add cold water, in moderate quantities, stirring each time, until the barrel is full.

Butter-Coolers.

Some time ago the manufacturer of a porous butter-cooler, Mr. A. Reeve, of Camden, N. J., sent us one of his coolers for trial. After careful testing, we find it to be a desirable means for cooling butter in hot weather. It is well known that the process of evaporation results in a reduction of temperature; and this is the principle upon which this cooler operates. It consists of a hollow piece of earthen-ware, as shown in figure 1. The bottom

is filled with water; and upon it is placed the plate containing the butter, which is covered by the upper part, also containing water; which gradually soaks through the porous substance, and evaporates from the surface, producing a temperature beneath the cover as low as 38 or 40 degrees, when the evaporation is active. When placed in an airy position, evaporation is greater, and the temperature proportionately lowered. Figure 2 shows the cooler complete. At fig. 3 is a cooler that can be made in a moment; a large plate is used for the stand. The plate is filled with water, in which a piece of brick, or flat tile, is placed. On this is set the plate of butter. A flower-pot, having a wooden plug to serve as a handle, is inverted over the butter, with its lower edge in the water. The porous pot absorbs the water, or it may be well moistened occasionally, and as it dries, it will cool the butter very rapidly. It should be placed in a draft of air, as in a cellar window.

Fig. 1.—SECTION OF COOLER.

Household Notes and Queries.

The readiness of the many members of the "American Agriculturist Family" to help one another, has been shown on many occasions, but never more strikingly than in the replies to "Recipes Wanted," in May last. One housekeeper wished a recipe for the "Queen of Puddings." We made her want known, and forthwith *forty*—save one,—39 of her sisters came forward to her help. The answers came from Maine to Florida and Texas in one direction, and from Vermont to Kansas and Colorado in the other, as well as from almost every intervening State. We had recipes in brief and *in extenso*; in the shortest possible prose, and the longest possible *verse*—both recipe and letter. If there is any one pudding that we ought to know about, it is

THE QUEEN OF PUDDINGS, and here is the recipe: One pint of bread-crumbs, one quart milk, one cup

Fig. 2. COOLER, COVERED.

sugar, butter size of an egg. Yolks of four eggs. Flavor with lemon, and bake as custard. Beat the whites of four eggs to a froth, mix with a cup of powdered sugar, and juice of a lemon. Spread a layer of fruit jelly over the custard while hot; cover with the frosting, and bake until slightly brown. To be eaten cold, with cold cream, or warm, with any sauce that may be preferred....So far as the composition goes, the many recipes were surprisingly alike, but the comments attached were very amusing, such as "The best pudding ever invented;" "The richest pudding known to cookery;"—But the funniest part of the whole matter is that the recipe started from this office several years ago,—so long ago that we had quite forgotten it, and now it comes back to us from nearly 40 housekeepers in the precise form in which it first appeared in our columns....In the same with the above paper we asked our friends for a

RECIPE FOR "SCRAPPLE," and this has been responded to by over 20 of our readers, but as that can be useful only in cold weather, when pigs are made into pork, we hold on to these until a more timely season....The promptness and the number of responses to these requests are very gratifying, as they show that housekeepers all over the country are ready to come to the help of any one of their sisterhood. We at the same time asked for recipes for the best manner of using

Fig. 3.—FLOWER-POT COOLER.

RYE FLOUR, ALSO FOR SALT RAISING FOR BREAD. We have received several of each of these, which will be given in due time. In the same month, May last, we had an article on "Women's and Children's Shoes," in which we gave a recipe for

SPONGE-BLACKING, such as is, or used to be, sold by all the druggists. A correspondent in Saco, Me., writes that he has made the same blacking for many years in his family, and finds that "the addition of one ounce of camphor to each pint of the blacking preserves it from drying hard, and cracking, as it will do without it." He also suggests that it is much less trouble to purchase the shellac-varnish ready-made at a paint-shop, and add the other ingredients. No doubt. But our recipes are intended for those who must start from first principles, many of whom are beyond the reach of those things which may be readily had in towns and cities.

A PORTABLE FOLDING WOOD-BOX.—From L. D. Snook.—In many localities, even in mid-summer, there are cool spells, in which a little fire in the evening is necessary, not only for comfort, but for health. Those who, with the approach of warm weather, put away all the fire-making appliances, may find a folding wood-box, one which may be used when needed, and set aside when not wanted, a useful household contrivance. The box referred to is shown in the engraving, and may be of a size suited to the wood used, and the quantity it is required to hold. It consists of a frame made of slabs of pine, or other convenient wood, an inch and a quarter thick, hinged together with a wooden pin, or by carriage bolts. The sides and ends are made of any heavy canvas or bagging, tacked to the frame, as shown in the engraving. If desired, the wood-box may be ornamented by the use of brass, or other bright-headed tacks, and the working of a monogram or initial letter on the sides and ends with some bright colored worsted. Such a wood-box will keep "dirt" from the floor, and when the time for which it is required has passed, it can be so folded as to occupy but a small space until a change in the weather to cooler may call it into use again.

FOLDING WOOD-BOX.

BOYS & GIRLS' COLUMNS.

The Doctor's Correspondence.

In trying to describe the Telephone I did not expect to make the younger boys and girls understand it, but I hoped by first stating some facts about sound, electricity, and magnetism (which is only a form of electricity), to give the older youngsters, and perhaps some who are not young, a general idea of it. Last month I told you about *induction*, and that a current of electricity in passing around a piece of soft iron would induce magnetism and make the bar of iron a magnet for the time, but as soon as the current stopped the soft iron ceased to be a magnet. It was also stated that a bar of steel could be made a magnet, and hold its magnetic power, forming a permanent magnet, and that a permanent magnet if passed into a coil of wire would induce a current of electricity in that wire. These points were described more in full last month; the object being to show you that electricity could make (or induce) a magnet, and on the other hand a magnet could make (or induce) a current of electricity. I must ask you at this time to attend to one more point, which will bring us

Near to the Telephone.

In figure 1 we have a bar of steel, *a*, which is a per-

manent magnet, and around it is a coil of wire, the wire being covered with silk or cotton to keep it from actually touching the steel; the ends of the coil, *b*, are in contact. If we now bring a piece of sheet-iron, *c*, near to one end of the magnet, its magnetism is disturbed, and at the same time a current of electricity will be started in the wire; on taking the sheet-iron away, the magnet returns to its former condition, and at the

Fig. 3.—THE TELEPHONE COMPLETE.

same time there will be a movement of electricity in the wire. The piece of sheet-iron induces a change in the magnet, and every change in the magnet induces a current of electricity in the wire. This may be repeated as often and as rapidly as we choose, and thus keep up a constant disturbance in the wire. Now one step further. In figure 2 we have the upper magnet and wire quite the same as in figure 1, but below at *d* we have another just such bar magnet, wound with wire in precisely the same manner, and the ends of the two wires, *b*, *b*, are joined together. By bringing the sheet of iron, *c*, near to the upper magnet, that as before stated will so affect it as to start a current of electricity in the wire. This current will pass through the coil around *d*, and as might be expected will disturb its magnetism, as would be shown by its action on another piece of sheet iron, *e*, placed near it. As *c* is moved up and down near the end of the upper magnet, the lower magnet would agitate *e* in the same manner. No matter if the wires between the two were several feet, or several miles long, the disturbance caused in the magnet, *a*, would be instantly repeated in the magnet, *d*. This is, in brief,

The Principle of the Telephone;

let us see how it is applied in use. Figure 3 gives the

Fig. 4.—INSIDE OF TELEPHONE.

appearance of the instrument. All that is seen is an affair of some hard-wood, with binding screws for attaching wires at one end; the other end is enlarged and hollowed out to form a mouth-piece; on looking into this mouth-piece you can only see a thin iron plate. In using the Telephone, one talks distinctly at the mouth-piece, while another, who has a similar instrument, at the other end of the wire—which may be five, ten, or fifty miles long—holds the mouth-piece to his ear, and hears distinctly the words that are spoken. You will recollect that I told you of speaking with a lady who was three miles or more away; just such an instrument as here shown was used. The real size of the Telephone is not quite six inches in length, and about three inches across the large end. But you will wish to know what is inside of the instrument.

The Machinery of the Telephone,

this is given in figure 4, which shows figure 3 divided lengthwise. Beginning at the upper or wide end we have the mouth-piece, and directly below this is a thin iron plate, the section of which is shown by the white line, *E*. As the plate used for taking the portraits called "ferrotypes," or "tin-types," was found to be of the right thickness—or more properly, thinness, this is used, though any other very thin iron would answer as well. In the center is a small steel rod, *A*, which is a permanent magnet, and this can be moved up and down to fix it in just the right position, by the screw seen at the lower end. We now notice the most important part, shown at *B*, which is a sort of spool, around which are wound many yards of fine copper wire, which is covered with silk; the two ends of which, *C*, *C*, pass down through what we may call the handle of the instrument, to the binding screws, *D*, *D*. This being the arrangement of the parts—how do they work? Let us go back to our figure 1, and we find we have the same parts that were described there; we have a steel magnet, and a coil of wire, but in the Telephone the coil is of much finer wire, and wound round and round a great many times to get the needed power. Then in place of the sheet-iron,

c, in figure 1, there is the very thin plate, *E*, figure 3, which is fastened at its edges. When one speaks at the mouth-piece, the motion of the air caused by the voice, sets this thin iron plate in motion, just as the parchment of the "Street Telephone," described in May, is made to vibrate by the voice. Of course these movements of this iron plate, or diaphragm, are very minute, but it does move, and at every motion or vibration, it disturbs the magnetism in the steel-bar, *a*, which in turn, sets up a current of electricity in the coil of wire, *B*, and we have just what was described in figure 1, over again, only in a vastly more delicate manner. But with one Telephone we can do nothing; to be of use the instrument

Must not only Hear, but Talk,

and to complete the affair, the instrument (figs. 3 and 4) is joined by means of wires attached by the binding screws, to another instrument precisely like it. These wires may be a few feet or a few miles long. Now you see there will be just such an arrangement as was shown in a coarse way in figure 2. A person speaks at the mouth-piece of one telephone, while another person holds the other telephone to his ear. The voice causes the iron plate to vibrate, that disturbs the magnet, which in turn starts a current of electricity along the wire; this current passes around the magnet in the other telephone, and affects that magnet, and that sets the thin iron plate in that instrument to vibrating. And here comes the curious part of the whole affair. The iron plate, or diaphragm, in the second telephone, will repeat exactly the motions of the first, and as the first is set in motion by the vibrations of the air made by the voice, the diaphragm in the second instrument will, by its vibrations, set the air near it in motion, and produce a precisely similar sound. If you at one telephone say, "Ah," the vibrations that this sound causes in the diaphragm, will be repeated by the diaphragm in the other telephone, which will set the air in motion to produce "Ah." What happens with this simple sound, takes place with all other sounds, and so exactly are the vibrations at one tele-

neighbors' farms.—This is not the kind of pigeon-keeping we would encourage, but there is a kind which the older boys may undertake with profit. Pigeons on a farm are generally, and justly, regarded as a nuisance. They are great feeders, and unless food is supplied to them, they will get it where they can, and in the garden and grain-field they are about as bad as so many crows, for they will go for the sown peas and grain. On the other hand, they are of such a quiet disposition, that, if food be furnished them close at home, they will not wander for it. A friend who raises pigeons largely, to supply his own table, and who is also a good gardener, and values the products of his gardens, informs us that he has no trouble with his pigeons, as he keeps food where they can always get it, and they do not stray away. Those boys who live near watering-places, or where there are hotels or good markets, may no doubt make pigeons profitable by supplying the demand for squabs, which always bring a good price at such places.

The pigeon-house is generally a make-shift affair, but those who go into pigeon raising as a matter of profit, should make proper arrangements for the birds, and not only provide them with a suitable house, but see to their proper feeding, and what is quite important, provide protection from cats, rats, and all other enemies. Our correspondent, Mr. L. D. Suook, Yates Co., N. Y., sends drawings of a house of this kind, which seems to provide properly for all requirements. The outside

Fig. 2.—A NEAT PIGEON-HOUSE.

Fig. 1.—INTERIOR OF PIGEON-HOUSE.

phone repeated by the other—the very tones of the voice, whether of speaking or singing—are reproduced,

Even Though Miles Away.

The Telephone is already coming into use, and has the great advantage over the telegraph in rapidity, and in not needing a skilled operator. Any one who can talk, can use it. Many are put up between offices and factories, and between the dwellings of merchants and their offices.... Just as I write this, news comes of another wonderful invention,

The Microphone,

which is a contrivance that magnifies small sounds, just as the microscope magnifies small things. It is said to enable one to hear even the step of a fly, and to magnify a whisper to a loud tone, while ordinary speech is a roar. This will help the Telephone wonderfully.

Pigeons and Pigeon-Houses.

Pigeons are usually the first pets the country boy has; a pair is given him, or he trades with another boy for them, fits up some kind of a pigeon-house in the peak of a barn, or in a shed, and his pigeons, while very interesting to him, soon become a pest on his father's and the

neighbors' farms.—This is not the kind of pigeon-keeping we would encourage, but there is a kind which the older boys may undertake with profit. Pigeons on a farm are generally, and justly, regarded as a nuisance. They are great feeders, and unless food is supplied to them, they will get it where they can, and in the garden and grain-field they are about as bad as so many crows, for they will go for the sown peas and grain. On the other hand, they are of such a quiet disposition, that, if food be furnished them close at home, they will not wander for it. A friend who raises pigeons largely, to supply his own table, and who is also a good gardener, and values the products of his gardens, informs us that he has no trouble with his pigeons, as he keeps food where they can always get it, and they do not stray away. Those boys who live near watering-places, or where there are hotels or good markets, may no doubt make pigeons profitable by supplying the demand for squabs, which always bring a good price at such places.

The pigeon-house is generally a make-shift affair, but those who go into pigeon raising as a matter of profit, should make proper arrangements for the birds, and not only provide them with a suitable house, but see to their proper feeding, and what is quite important, provide protection from cats, rats, and all other enemies. Our correspondent, Mr. L. D. Suook, Yates Co., N. Y., sends drawings of a house of this kind, which seems to provide properly for all requirements. The outside (fig. 2) is 10 by 16 feet, 8 feet high at the eaves; it has a tight, shingled roof. Lighting-boards are provided, as shown in the engraving, are four inches wide, and supported by brackets at a distance of six inches from the side of the building. The engraving shows a door in the end with a window at each side; the matter of windows may be arranged according to convenience, all that is necessary being to have the inside fairly lighted. Figure 1 shows one side of the interior, where there are platforms, *K*, *K*, upon which the birds enter, and which hold three nesting and hatching boxes, *P*, *P*. These boxes are 4 feet long, 9 inches wide, 6 inches high in front, and 10 inches high in the rear, and are provided with a sloping hinged cover. Each of these is divided into five

compartments, with an entrance to each in front, which opening is 3 inches wide by 4½ inches high. Roosts, *B*, *B*, are provided, which are hinged to the platform, *K*, and held in place by the upright, *E*; these roosts may be let down when it is desirable to examine the nests by means of a step-ladder placed against the platform. On the lower tier, on each side, are but two hatching boxes, to allow of a number of roosts, of strips a foot long, to be placed between them. At *T*, is shown a box for storing feed, which should be given to the birds within the house, in stormy weather. A building of this kind should be placed where it can be shaded by trees in the heat of the day, and in a quiet place, where the nesting birds will not be disturbed by noises. Besides abundant feed, the birds should be constantly supplied with water, and have a mixture of salt, sulphur, and gravel, placed where they can always get at it.

Aunt Sue's Puzzle-Box.

ENIGMATICAL BOUQUET.

1. Part of the rainbow. 2. What some of us love to kiss. 3. A sugared letter. 4. What children love, and a bunch of hair. 5. A trap and its victim. 6. A crystal of water and a tear. 7. Went up.

PUZZLE.

My fifth is one-half of my first,
My whole is divided by two,
My second's the same as my fourth,
Now guess it you surely can do.
To aid you more hints I will give:
Twice my third is a tenth of my first,
My whole of five letters is seen,
Which all should be, even the worst.

JUVENIS.

SQUARE WORD.

1. Apt. 2. A vegetable. 3. A direction. 4. A girl's name.

CROSS-WORD.

My first is in butter but not in milk.
My next is in satin but not in silk,
My third is in rain but not in snow,
My fourth is in fast but not in slow,
My fifth is in ache but not in pain,
My sixth is in snow but not in rain,
My seventh is in light but not in heat,
My eighth is in sofa but not in seat,
My ninth is in Autumn but not in Fall,
My tenth is in whole but not in all,
My eleventh is in word but not in rhyme,
My whole names a man of ancient time. ISOLA.

NUMERICAL ENIGMAS.

(S. W. W. offers the following enigma as a stumper.)

- I am composed of 39 letters:
My 13, 2, 28, 11, 37, means time and pains.
My 26, 1, 20, 13, 39, to be acquitted.
My 10, 18, 3, 33, is a blemish.
My 29, 17, 5, 24, to polish.
My 38, 30, 32, 12, 4, 9, 20, 36, 34, to pass.
My 23, 6, 21, 14, a side-piece.
My 7, 27, 8, 22, 19, 30, 25, a butcher.
My 31, 16, 35, 14, is a kind of cloth.
My whole is a familiar quotation from Young's "Night Thoughts." S. W. W.
- I am composed of 12 letters:
My 4, 11, 5, sometimes goes with a kiss.
My 12, 8, 7, 3, is a planet.
My 12, 10, 9, 6, is to sap.
My 1, 2, 9, is a propeller.
My whole is a common flower. FRANK KENNEDY.

A VERY EASY ENIGMA.

- I am composed of 9 letters:
My 5, 8, 3, 4, is something that you are sure to find in the woods.
My 6, 7, 2, is an animal.
My 1, 9, 7, 2, is what you see in winter.
My whole is a very nice vegetable. P. T. VIBERT.
- I am composed of 11 letters:
My 8, 2, 11, is the shepherd's deity.
My 9, 5, 8, is the name of a vine.
My 1, 7, 4, is a pronoun.
My 1, 10, 3, 6, is what most cows have.
My whole is a musical instrument. MYRA A. HANLON.

ANSWERS to the Puzzles in May number will be given next month.

ABOUT THE PRIZE ENIGMA.

One letter received on the subject, will make a very good introduction:

"Dear Aunt Sue:—I send you with this, the answer to February prize enigma. You are the one that should get a premium for getting up such a puzzle; it superseded the Eastern question and the silver wrangle at our house. Geography and political economy were put aside, and etymology came to the front. We don't think that Miss Clara Josephine will have a very heavy contract in making the drawings next May.—Respectfully Yours, G. M. T."

Miss C. J.'s aid was not called into requisition, for only seven answers were sent. Very pleasant letters accompanied most of them, telling the process by which the desired end was attained.

The answer to the enigma is, "Pungled; said especially of grain which has lost its juice."

The names of the patient and persevering solvers are: LYMAN STEDMAN, Jedd, Jefferson Co., Ohio; H. A.

FRINK, Westerly, R. I.; H. E. WHITNEY, Monticello, Sullivan Co., N. Y.; GEO. M. TAYLOR, Riverside, Burlington Co., N. J.; CYRENE GRIFFIS, Montrose, Susquehanna Co., Penn.; J. A. BOSTON, Newburyport, Mass., and JOHN B. BAKER, Concord, Merrimac Co., N. H.

ANSWERS TO PUZZLES IN THE APRIL NUMBER.

ALPHABETICAL QUERIES.—1. V inverted makes a caret (carrot). 2. Pea and tea (P and T). 3. B (bee). 4. U (you). 5. B, C, and R (be, see, are). 6. J (jay). 7. I (eye). 8. G (gee). 9. D (dee). 10. Y (why). 11. W (double you). 12. Q (que). 13. Red C (sea). 14. X specked (expect). 15. Dutch S (duchess). 16. Bar on S. 17. L (ell).

CHARADE.—C—A—P—Cap.

NUMERICAL ENIGMA.—Learning is to the studious, riches to the careful, power to the bold, and heaven to the virtuous.

CROSS-WORD.—Constantinople.

ALPHABETICAL ARITHMETIC.—(314)369501(2769).
Key—Palmerston.

PI.—Black lead does not contain a single particle of lead, but is composed of carbon and iron.

DROP-LETTER PUZZLE.—Never cut out a piece of a newspaper till you have looked on the other side.

TRANSPPOSITIONS.—1. Teach, cheat. 2. Rome, more. 3. Broad, board. 4. Desert, rested. 5. Patch, clasp.

SQUARE WORD.

CONCEALED FISH.

Key—Palmerston.

Forward.

Backward.

Correspondents will save time, if they will address their letters (to Aunt Sue) to Rowayton, Fairfield Co., Conn., from July to December of this year. But please remember that AUNT SUE is not Orange Judt Co.; the latter must be addressed at 245 Broadway, N. Y. City.

The Young Microscopist's Club.

A share of last month's talk was given to an account of a common insect parasite upon chickens, and it was there stated that those animals that fed upon other animals, and those plants that fed upon the juices of other plants, were termed *parasites*, and we may add that those having this manner of living, are called

Parasitic Animals and Plants.

Not only do the higher animals afford homes for insect and other parasites, but *insects themselves* are preyed upon by other insects, a matter no doubt of much discomfort to the insects thus visited, but one of real importance to us, who are obliged to look upon some insects as our enemies—as we shall presently see. A remarkable instance of an insect being troubled by parasites, was brought me a short time ago by a gentleman living in Westchester Co., not far from New York City. He brought specimens of the Colorado Potato-Beetle—now generally known as the “Potato Bug”—so completely covered by small creatures, that the beetle itself could not be seen; it was even more thickly covered than the beetle at *a*, figure 1, which shows both of the natural size. The little creature is

A Parasitic Mite,
which might be called the “Potato-Beetle Mite,” were it not found on other beetles also. I think that I have already told you that mites differed from the true insects, among other points, in having the body all in one piece. This mite was first described by Prof. Riley, who gave it the scientific name of *Uropoda Americana*, there being other species in Europe. The name *Uropoda* is from Greek words meaning *tail* and *foot*, on account of a peculiar tail-like arrangement by which this attaches itself to the beetle. The engraving is from Mr. Riley's work on “Potato Pests”; *b* gives the mite enormously magnified, showing its underside. To hold fast to the beetle, the mite has a pair of remarkable organs, which, when not in use, lie just under the skin, between the legs, as shown by the lines in *b*, but when in use, they are extended as in *c*, reaching out beyond the head; each has a minute claw at the end, more plainly seen at *d*. We now come to the “tail-foot” part, from which the creature is named. In Europe this was long supposed to be a kind of silk, to enable the mite to hold fast with, but Mr. Riley has discovered that the thread is the dried excrement of the mite, made to serve as a sort of anchor; the thread of this is shown at *e*. As you may suppose, so many parasites as at *a*, all feeding upon it, soon

Put an End to the Beetle,

and this brings us to a very interesting thing concerning injurious insects. Scarcely one of you, who live in the country, at least in the Middle and Northern States, but has seen the Colorado Beetle, or “Potato Bug,” and those who live elsewhere have heard much about it; how rapidly it ate up the potato vines, and if the insects were allowed to have their own way, we should be obliged to go without potatoes. To get potatoes at all, in many parts of the country, the farmer is obliged to poison the beetles. But when an insect increases in large numbers, its natural enemies increase also, and though most people look upon birds to keep insects in check, these probably do but little as compared with

Their Insect Enemies,
which attack and feed upon them in one form or another, whether in the egg, the larva, the pupa, or perfect state. Besides a spider and the mite here described, there are known to be *over two dozen* true insects that prey upon the potato-beetle. This beetle, being so destructive, has been watched more closely than others, but it is found to be the case that, whenever an injurious insect gets to be very abundant, its insect enemies increase rapidly also. Now is not this a wonderful arrangement of things? By growing millions of acres of potatoes, we allow of the increase of an insect that, when it only had certain wild plants to eat, gave no trouble, but with this food provided for it, it multiplied so as to threaten to stop potato culture; but other insects come to our help in dozens, and if we could afford to wait, the evil might in time be cured without the use of poison. As it is, we are greatly aided by other insects. Does not this look as if some Great Mind really directed these matters?... Though I have said so much about parasites, I must just mention another, a dozen or more being sent every season as a great wonder. Figure 2 shows what a great many of you must have seen; a

Fig. 2. TOMATO-WORM.

Tomato “Worm,” or Caterpillar,

is a great, green, unpleasant-looking, but harmless creature to all but plants, and those it eats heartily. These caterpillars are frequently seen almost covered with white things, which most persons take for eggs. They are really little cocoons. When the caterpillar was young, a very tiny fly stung it and dropped in her eggs; these eggs hatched, and numerous little caterpillars or maggots, lived inside the big one; when they reached their full size, they ate their way out, and spun these little nests, and went to rest. If you find a “worm” thus loaded, place some of these cocoons under a glass, and you will no doubt be able to see and examine the perfect little fly. It is very small, and you might not notice it unless on the watch for it.... Last month I promised to say something

About Mounting Objects.

In March last, I described one method of mounting seeds and other opaque objects, and will now try to answer those who have inquired about transparent objects, or those seen by transmitted light, and as our microscope

Fig. 1.—POTATO-BEETLE PARASITE (*Uropoda Americana*.)

and our talks about it are for beginners, I can only give you the simplest methods, and you will find that these will require all the time and skill you will care to give, while the procuring of the materials will be more of an expense than some will care to go to. In the first place, you will need some

Glass Slides;

these are sold at the instrument stores, and for microscopes of high power should be of the finest plate-glass; for your purpose, the clearest glass that you can find among the glazier's scraps will answer, and you can get the glazier to cut them for you in pieces three inches by one, which is the usual size, though some prefer them $2\frac{1}{2} \times \frac{3}{4}$ inch. Then the objects must be covered with thinner glass; for nice preparations, to be used with high powers, thin glass covers are made on purpose, varying from $\frac{1}{50}$ to $\frac{1}{150}$ of an inch in thickness; these are round or square, one half to one inch across, and cost from \$1.25 to \$3, or more, an ounce, according to thin-

ness. These must be used for high powers, but to mount objects for our Microscope, while it will be neater and better for those who can afford it to have this thin glass, you had better begin with the very thinnest you can find, and practice at first with that. You will also need some

Canada Balsam,

which those of you who live where there are Balsam Fir trees, will know all about, and that it is found in blisters in the bark of these trees, and is easily collected by cutting these swellings, and squeezing out the honey-like liquid into a spoon. Most of you will have to get it of the druggists; an ounce in a wide-mouthed vial will last a long time. Canada Balsam is a natural mixture of a clear resin with oil of turpentine, and when exposed, the turpentine will evaporate and leave the solid resin. If left exposed, it will, after a time, become very thick and finally solid. If the vial is stopped by a cork, it will be apt to cement the cork in firmly, and it will be well if you can find some kind of a tin box, to go over the mouth of the bottle like a cap.

Other Articles that may be Needed,

are a small bottle of Oil (Spirits) of Turpentine; one of Alcohol; and one of Solution of Potash (Liquor Potassae of the druggist). Besides these, you will need small forceps, or tweezers, and mounted needles, already described in the sheet that goes with the microscope. A brick or piece of soapstone that you can warm on the stove, or in the oven, will also be needed, and it will be convenient to have a contrivance for holding the slides when hot; for this the spring clothes-pins will answer, arranged by cutting off one arm, as suggested by Prof. Phin, as shown in figure 3. After all this preparation,

Fig. 3.—FOR MOUNTING OBJECTS.

which looks more forbidding than it really is, let us proceed to

Mount a Fly's Wing.

First clean your slide thoroughly, and put it on the warm brick or other contrivance for warming, until it is warm enough to make the balsam very thin; drop on the center of the slide a single drop of the balsam, from a small glass or a wooden rod, which is to be kept in the vial for the purpose. If any air bubbles appear, remove them by means of a needle. Then take the wing up by the forceps, and place it gently on the balsam, putting it on in such a manner that no air will get between it and the balsam; drop on a very little more balsam, and then carefully put on the cover, which has been warmed; the cover should be put on, one edge first, and gradually let down upon the balsam so as to not inclose any air; press the cover down slightly, and put the slide away in a warm place, such as a shelf near the stove, until the balsam becomes quite hard. Some of the balsam will no doubt project beyond the cover up on the slide; when this gets hard, most of it can be easily scraped off, and the rest removed by a little turpentine on a cloth. With some objects it may be necessary to hold the cover down with a clothes-pin clip while hardening. Sometimes the wing or other object will not take to the balsam readily, but leave air between the two; in this case the object is first soaked awhile in oil of turpentine, which usually removes the difficulty.

Some Small Insects Entire,

as well as the feet and other parts of large ones, are sometimes mounted in Canada Balsam, but first require soaking in the potash solution to make them more transparent; they are then soaked in water to remove the potash, then in strong alcohol to take out the water, then in turpentine to get rid of the alcohol, and finally they are ready to go into the balsam. When the object is mounted, the slide may be covered on one side, or both, with colored paper, leaving circular openings over the object, and the label written on this, or the glass may be left uncovered, and a small paper label attached with gum tragacanth, or paste.—Much in the way of mounting must be learned by practice; those who wish to know of other methods, should have some work on the subject. One of the best works, at a moderate price, is Prof. John Phin's “How to Use the Microscope.” Price 75 cents.

More About Birds.

The account given last month of the strange Bower and Gardener Birds, has interested not only the youngsters for whom it was intended, but many of our older readers have shown much interest in them, and would like to know more—especially about the Gardener Bird. That being a quite new discovery, we gave the fullest account we could find, and we must wait until some other naturalist visits the island where it is found. Some of the youngsters wish we would tell more about and give more

almost always very unlike in this. So naturalists, in describing birds, take characters that are more permanent: the form of the head and bill; the legs and feet; the wings and tail, as to number of certain quills, and other points with which color has nothing to do. You are not to understand from this that color is of no importance in describing birds, but that while it is the first thing that strikes your eye, you should, in observing the birds you see, take notice of other points. The picture here given of a group of our native birds, illustrates what has been said. If we could show you the birds themselves, you

rear our young on insects and worms, we like a little fruit with our meat, and go to the trees and pick out a few wormy cherries—pop—bang—dead Robins! Then what is more than all, the fall horticultural meetings pass resolutions against us, and call us rascals; but some have the grace to say that we do make a good pot-pie. If these men would only let us mind our own business, we could put money in their pockets."—So much for the Robin's story. Watch him carefully, and see if he is not right. The bird on the ground in the picture, though often called Ground or Marsh-Robin, does not belong to the same

pictures of our common native birds, and we are always glad to have our young friends express their wishes. While the greater number of our junior readers were born in, and live in the country (and we hope that they may find it best to stay there), still very many go to the country for a few months only, in the summer; and to these all the country objects, the trees and flowers, the birds and insects, seem quite different from what they do to those who are always among them; and it often happens that those who are in the country for a short time only, learn more about, and really know more about, country objects than those who are constantly among them, just as a country person visiting a large city will see more of the city's "sights," than one who lives there will see in ten years. There is one trouble about giving pictures of birds. When you see a bird on the wing, or perched upon a twig, the first thing that strikes you is its *color*. This is particularly the case with such brilliant birds as the Scarlet Tanager, which glows as it flits among the green leaves like a ball of fire. When we show you a picture of this bird, no matter how carefully it is drawn and engraved, you see only black and white, and it does not bring the brilliant Tanager to your mind at all. But you must recollect that color is only one of the marks by which birds are known, and one of the least constant. Birds change their plumage with age, and with the season; while the sexes, male and female, are

would have a quite brilliant display of colors: red, black, yellow, white, and various shades of brown, would catch the eye at once. The bird most prominent in the picture is one of the best known in nearly all parts of the country. If its breast were red, you would at once recognize the familiar Robin-red-breast. Our Robin is a very different bird from the English Robin, and is not very closely related. When our ancestors came to this country, they gave to the plants, the birds, etc., that most resembled those they had left at home, the familiar home names, and gave that of Robin-red-breast to a bird about twice the size of the English Robin. If the Robin could write or speak, what an account he would give of us "featherless bipeds." It would run something after this style: "These animals called men, who are born without feathers, and are obliged to rob the poor sheep to keep themselves warm, are very glad to see us in early spring; they praise our song, and allow us to come upon the trees about their houses because we take the caterpillars to feed our young; they let us follow the plow, for we pick up lots of grubs and worms, and they only praise us during the spring months. They print in their papers that each one of us destroys a worm every 2 1/6 minutes; and sometimes tell how far the worms, put end to end, would reach, that we require to rear a nest of young. We are very lovely birds until cherries are ripe; but then, if after working hard all the spring months to

family with the common Robin, but to the Finches. Its common name in some parts is "Towhee Bunting," and in others, "Chewink." It is common in most of the Eastern States; its colors are very distinct, being mainly black and white, with some chestnut-brown on the sides. It builds its rude nest on the ground, and is essentially a ground bird. The note of the male is *low-he'e'che'de*, which he gives out as a warning when the nest is approached. The Cow-bird, or Cow Blackbird, the one that appears in the center upon a branch, and in a fluttered state, is not a very pleasing bird. Its general color is shiny black and purplish-brown, and is often to be seen in pastures with cattle, following them closely that it may get at the insects as the cattle eat away the grass. This is a mean and lazy bird, building no nest of its own, but dropping its egg in the nest of some other bird, usually that of an innocent Warbler, which poor creature hatches out the Cow-bird with her own young, and the intruder often grows so fast as to crowd the rightful owners out of the nest. The bird at the upper right-hand part of the picture is one of the numerous Warblers, the "Magnolia Warbler," or "Black and Yellow Warbler." It is well marked by its yellow breast streaked with black. The little fellow, looking in from above, is "Blackburn's," or the "Hemlock Warbler," and is the most beautiful of all the Warblers, on account of the intense orange or flame-color of its throat; the back and crown being black.

A MONG the principal dealers in materials used by makers of fertilizers, and probably the most extensive of all, is Mr. GEO. E. WHITE, of New York (159 Front street). He also supplies lots of five or ten tons of his own brands of Ammoniated Superphosphate, dissolved bones, potash, soda, ammonia, etc. A certificate and analysis is given with every invoice which he sends out.

Protruding Toes.

PARENTS, you need no longer throw away your children's shoes before they are half worn on account of holes through the toe. Either the **SILVER** or Beautiful **BLACK** Tip will prevent this.

TEAS

This is a combination of capitalists to supply consumers only throughout the United States with **PURE TEAS** at prices never before known, on the installment principle, by getting up clubs. Send for New Price-List.

CONSUMERS' IMPORTING TEA CO.,
P. O. Box 5509. No. 8 Church St., New York City.

W. A. DROWN & CO'S WAGON & REAPER UMBRELLAS

A Protection During Harvest.

No. 246 Market St., Philadelphia. No. 498 and 500 Broadway, New York.—Send for a Price-list.

EVERY lady should have our Combination Sewing-Machine Screw-Driver, Thread Cutter, Seam and Binding Upper, 25 cts., by mail. **Automatic Eye-Glass Holder**, 25 cts., by mail. Endorsed by *Agriculturist*; see page 8, January Number, 1878. Circulars Free.

AND NOT WEAR OUT.
By mail, 30 cts. J. S. BIRCH & CO., 38 Dey St., N. Y.

Peter Henderson's Books.

Read what practical people say, who know what books they need, and who also know when they get such books. The following extracts are taken from letters, of which very many have been received, giving testimony to the value of the works mentioned. No better books, or those more practically useful, have ever been published upon the subjects of which they respectively treat.

GARDENING FOR PROFIT.

Price, post-paid, \$1.50.

EXTRACTS FROM LETTERS.

"By following the plain directions given in your books, 'Gardening for Profit,' and 'Practical Floriculture,' I have got into a good paying business, having succeeded far beyond my most sanguine expectations, both with vegetables and flowers."

Feb. 2, 1877. **ALBERT WILLIAMS, Sharon, Pa.**

"In 1870 I purchased your book, 'Gardening for Profit,' and turned about five acres of my farm into vegetables for our market here, and with such success, that the

profits from those five acres have been more, annually, than that of my whole farm of 150 acres.

Dec. 3, 1876. **HENRY G. STEWART, Buffalo, N. Y.**

"Your work, 'Gardening for Profit,' is to all other similar works, what Blackstone is to all other law books. Jan. 16, 1878. **JOHN T. CRIST, Independence, Mo.**"

"I have both your works, 'Gardening for Profit,' and 'Practical Floriculture.' I have been repaid a hundred times for the money they cost."

Sept. 8, 1876. **M. E. LEA, Brighton, Maryland.**

"'Gardening for Profit,' if valuable to American gardeners, must be indispensable to foreigners, as all know the mistakes likely to be made, which your instructions show so well how to avoid."

Aug. 29, 1876. **JOHN MASSEY, Batavia, Ill.**

"Your suggestions in 'Gardening for Profit,' induced me to try raising vegetables here for northern markets, and though prices have been unusually low for the past two seasons, yet I think I can now see my way clear to a very profitable trade."

Jan. 10, 1877. **MICHAEL SHANNON, Norfolk, Va.**

GARDENING FOR PLEASURE.

Price, post-paid, \$1.50.

EXTRACTS FROM LETTERS.

"Your books on horticulture have been of great value to me, the article on Strawberry Culture, in 'Gardening for Pleasure,' alone, has been to me worth ten times its cost this season."

July 2, 1877. **GEO. I. STREATOR, Garrettsville, Ohio.**

"Your work, 'Gardening for Pleasure,' contains more plain, practical information than anything I ever read on the subject—and I know of what I speak, having been gardening for 30 years."

Jan. 23, 1877. **A. C. LANIER, Madison, Ind.**

"Send me your 'Gardening for Pleasure.' I have both of your other works, and would not exchange them for their weight in gold, if I could not otherwise replace them."

March 5, 1877. **LOUIS STEGLER, Harrisburg, Pa.**

"'Gardening for Pleasure' is an excellent supplement to your other works, and will prove a good friend to amateurs in gardening, who greatly need its plain and practical teaching."

Dec. 6, 1876. **MARIE HOWLAND, Hammon, N. J.**

"'Gardening for Pleasure,' by the author who has already done so much to instruct us of how to make pleasant our country homes, is certain to receive a warm welcome; no subject seems to have been overlooked."

Jan. 8, 1877. **HENRY C. BAKER, Wilmington, Del.**

"I have read with great interest your very well written book, 'Gardening for Pleasure.' It is full of condensed information, both for the amateur and even the more experienced in gardening, and I have no doubt it will give pleasure to thousands, as it has done to me."

Dec. 3, 1876. **JAMES HENDRICKS, Albany, N. Y.**

"I am just in receipt of your 'Gardening for Pleasure,' and if it prove half as interesting to me as your other works, it will be something I cannot well do without."

Nov. 24, 1875. **PHILIP HENRY BROWN, Portland, Me.**

PRACTICAL FLORICULTURE.

Price, post-paid, \$1.50.

EXTRACTS FROM LETTERS.

"Being a novice, I depended altogether on your book, 'Practical Floriculture,' which I have taken solely as my text book, and my success has surprised me."

Jan. 11, 1878. **JOHN C. BONDE, Lexington, Va.**

"I have run my greenhouses mainly by the instructions in your book 'Practical Floriculture,' and so far with great success."

April 10, 1877. **WILLIAM A. BEERS, Fairfield, Conn.**

"I have to thank your 'Practical Floriculture,' which has been the means of enabling me to engage in a business which I trust before long will become as profitable as it is pleasant. I have 2 large greenhouses now stocked with fine plants, entirely propagated and grown according to your directions, which, when disposed of at even moderate prices, I think will pay."

Mar. 15, '76. **BENJAMIN C. LODER, Cleveland, O.**

"The system of propagating plants, described in your 'Practical Floriculture,' I have followed to the letter, and I doubt if even your own success has been any better than mine."

Jan. 6, 1878. **L. C. JOHN, St. Paul, Minn.**

"With the instructions received from your works, 'Gardening for Profit,' and 'Practical Floriculture,' I am doing a little both in vegetables and flowers. In both I have been successful, but particularly in flowers."

June 8, 1877. **L. C. BARDWELL, Boston, Mass.**

"I have nearly all works on gardening, both American and foreign, but I find, whenever I am in a quandary, I look into your little work, 'Practical Floriculture.'"

July 25, 1876. **J. D. GRAHAME, Denver, Colorado.**

ORANGE JUDD CO., 245 Broadway, New York.

TURNIP SEED.

All grown from carefully selected Roots.

The following varieties will be mailed *post-paid* upon receipt of price affixed: Early White Dutch, White Strap-leaf, Red-top Strap-leaf, Cow-horn, Improved American Rutabaga, Long White French, Sweet German, Large Yellow Globe, 0 cts. per ounce, 25 cts. 4 ounces, 75 cts. per pound. Prices for larger quantities to dealers, either in bulk or packets for retailing, will be given upon application.

Our Turnip Seed Circular,

giving many hints of the great value of this crop and full directions for its cultivation. Also a list of **VEGETABLE and FLOWER SEEDS** for sowing in August and September, mailed free.

FLOWER SEEDS FOR FALL SOWING.—20 varieties Hardy Annuals and Perennials, \$1.

Our **AUTUMN CATALOGUE OF DUTCH BULBOUS ROOTS and SMALL FRUITS**, about 50 pages, beautifully illustrated, will be ready for distribution Sept. 1st. A copy will be mailed to all applicants enclosing **Ten Cents**; regular customers supplied gratis.

SILVER HULL BUCKWHEAT,

A great improvement upon the ordinary variety. It continues in bloom longer, matures a few days sooner, and yields nearly or quite double under the same conditions. The grain is of a light gray color, varying slightly in shade, and the corners are much less prominent than in the ordinary variety, while the husk is thinner, thereby saving from 15 to 20 per cent. waste in the process of manufacturing into flour, which flour is whiter and more nutritious. Price per bushel, \$2.50; half bushel, \$1.50; peck, \$1.00; 3 lbs., by mail, \$1.00. Address

B. K. BLISS & SONS, P. O. Box 5712,
34 Barclay Street, New York.

NEW CROP TURNIP SEED; all standard varieties, at lowest prices. Am. Ruta Baga, 55c. per lb., post-paid. Catalogue of Fall Seeds mailed Free to every applicant.
BENSON, MAULE & CO., 223 Church St., Philadelphia.

FOREST TREE SEEDLINGS

For the Fall of 1878. By mail, post-paid, and warranted to arrive safely to any P. O. in the U. S. or Canada.

	Per 100	Per 1,000
Sugar Maple, 4 to 6 inches.....	\$.50	\$3.00
Soft Maple, 4 to 8 ".....	.75	5.00
American Beech, 6 to 8 ".....	.75	4.00
White Elm, 6 to 9 ".....	1.00	5.00
Yellow Birch, 6 to 9 ".....	.75	4.00
Black Ash, 6 to 9 ".....	1.00	6.00

20 varieties tree seeds, native and imported, \$1.00. Also Cuttings, European Larch and Evergreen Seed. Order now. Send Registered Letter, P. O. Money Order or Draft, at my risk. **Caution.** Do not send money in letters without registering. Send for a price list. Address
W. W. JOHNSON, Central Lake, Antrim Co., Mich.

CHOICE BUTTER.

(From Massachusetts Agricultural College Farm.)
"AMHERST, MASS., Feb. 9, 1878. VERMONT FARM MACHINE COMPANY: We are so well pleased with the Cooley Creamer that I feel bound to say a word in its favor. It takes us only twenty minutes to churn, and the extra yield of butter is wonderful. I have cheerfully recommended it to the Japanese government above all other systems.

Yours very respectfully, A. A. SOUTHWICK, Farm Supt."
Address for circular,

SAFETY, COMFORT, ECONOMY,

SECURED BY USING

THE RUBBER CUSHIONED AXLE.

It lessens vibration, jolting, and pounding; stops splitting of hubs and spokes, and breaking of rims and tires; prevents crystallization of all the metal parts; relieves the vehicle from undue strain when meeting obstructions or passing over uneven surfaces; assures accuracy and precision in the movement of the wheels; muffles noise and rattle; prevents violent dilation of the springs, thereby lessening motion; possesses special advantages for invalids or delicate persons: reduces wear and tear to a minimum.

AND MARKS

a stride, the greatest ever made, towards perfecting wheeled vehicles.

Can be applied by any builder to old work as well as new. Correspondence solicited.

ADRIANCE REAPER ON THE ROAD.

ADRIANCE PLATT & CO.,

Manufacturers of Buckeye Mowers and Reapers, and the Adriaance Reaper,
165 Greenwich St. (near Courtlandt St.), N. Y. Manufactory, Poughkeepsie, N. Y.

The ADRIANCE is a light, strong, simple, efficient REAPER, which will work well in all kinds and conditions of grain, and combines more good points than can be found in any other. It has a folding platform, and is in all respects worthy to rank with the Buckeye Mower.

The BUCKEYE has for 21 years held its position as the LEADING MOWER and REAPER of THE WORLD, because it is superior to all others in the principles of its construction. It is the only machine which has given entire satisfaction to the farmer; its AVERAGE DURABILITY has been MORE THAN DOUBLE that of others, and the COST OF KEEPING IT IN REPAIR LESS THAN ONE-HALF.—Prices Reduced to the lowest point at which the high standard of excellence in material and workmanship can be maintained. Descriptive Circulars forwarded by mail.

monds** (a specialty). Articles in silver, jewelry only
in gold of 14 carats and upward. No deception in quality or
price. Prices reasonable. Over 30 years at the same place.
H. N. SQUIRES, 97 Fulton St. N. Y. City.

Three Most Important Works

NOW IN PRESS.

Winter Greeneries at Home.

By REV. E. A. JOHNSON, D.D.

FINELY ILLUSTRATED. 12mo. PRICE, POST-PAID, \$1.00.

This work differs from most other works on winter gardening in giving the results of actual practice. The title Winter Greeneries better expresses the scope of the work than would that of Window Gardening. All can make their rooms cheerful with green, while to successfully cultivate

many flowers requires more skill than the majority of people possess; still flowers are not omitted. A small but judicious selection of easily-procured and easily-managed plants is given, with which to enliven the greenery.

House Plans for Everybody.

By S. B. REED, Architect.

PROFUSELY ILLUSTRATED. 12mo. PRICE, POST-PAID, \$1.50.

This is a valuable work which meets the wants of persons of moderate means, and we predict that it will prove one of the most popular architectural books ever issued. It gives a wide range of design from a dwelling costing \$250 up to \$3,000, and adapted to farm, village, and town residences. Nearly all of these plans have been tested by practical workings. They provide for heating, ventilation, etc., and give a large share of what are called Modern Improvements.

One feature of the work gives it a value over any similar publications of the kind that we have seen. It gives an estimate of the quantity of every article used in the construction, and the cost of each material at the time the building was erected, or the design made. Even if prices vary from time to time, one can, from these data, ascertain within a few dollars, the probable cost of constructing any one of the buildings here presented.

TALKS ON MANURES.

By JOSEPH HARRIS, M. S.,

Of Moreton Farm, Rochester, New York. Author of "Walks and Talks on the Farm," "Talks on Farm Crops," "Harris on the Pig," etc.

12mo. PRICE, POST-PAID, \$1.50.

In the present work Mr. Harris continues the talking style which he has made entirely his own in agricultural teachings. He also continues our acquaintance with the "Deacon," the "Doctor," and the "Squire," and others of his neighbors who have been made, through the medium of these Talks, almost as well known as the author himself. While we have no lack of treatises upon artificial fertilizers, we know of no recent work in which the main stay of the farm—the manure made upon the farm—is treated at all satisfactorily or thoroughly. If this work should do nothing more than convince farmers throughout the country that the value of manure depends upon the quality of the food they feed, rather than upon the kind of animal that eats it, it will accomplish much.

But it does a great deal more than this; starting with the question,

"What Is Manure?"

It runs through in sufficient detail every source of manure on the farm, discussing the methods of making rich manure; the proper keeping and applying it, and especially the

Uses of Manure,

and the effects of different artificial fertilizers, as compared with farm-yard manure, upon different crops. In this the author makes free use of the remarkable series of experiments instituted years ago, and still continued, by Lawes and Gilbert, of Rothamsted, Eng. The

Remarkable Tables

In which the results of these experiments are given, are here for the first time made accessible to the American farmer. In fact, there is scarcely any point relating to fertilizing the soil, including the suitable manures for special crops, that is not treated, and while the teachings are founded upon the most elaborate scientific researches, they are so far divested of the technical language of science as to commend themselves to farmers as "practical" and inhospitable to science as the Deacon himself. The book should have a hearty welcome from every farmer, except the fortunate few who cultivate soils, the natural fertility of which is not yet exhausted.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from p. 247.

Tumor on Cow.—"H. L. W.," Sandy Hook, Ct. The "bunch on the cow's belly" is probably an abscess, in which case it should be poulticed, and opened when it points. It may, however, be due to an entirely different and much more serious cause. You had best have it examined by a competent veterinary surgeon.

Alsike Clover.—"F. R. G.," Waynesboro, Ohio. Alsike clover may be sown in the same manner as common red clover. It is late in blossoming, so that it is ready for cutting with timothy, which is an advantage. It also succeeds best on moist ground, where red clover is often winter-killed. But we have not yet heard of a case where those who have tried it prefer it to red clover.

Loss of Feathers.—"D.," Poultry will frequently drop their feathers when over-fed upon corn, buckwheat, or other heating food. The remedy is to feed only chopped cabbage or turnips, or turn them into a grass field for a few days. A few pills of castile soap, or half a teaspoonful of castor oil, will be of benefit.

Death of Sheep.—"H. D. G.," Bremer Co., Iowa. When a sheep is poisoned, convulsions—a symptom of disease of the brain or spinal cord—rarely ensue. In examining a dead animal for the cause of death, the brain should be looked to, especially when the animal is convulsed or turns up the eyes forcibly. The skull should be sawn through around it on a line with the ears, and the top carefully removed. In your case, when no symptom but convulsions were noticed, the presence of parasites in the brain might be suspected, and the trouble was probably incurable.

Patent Fences.—"G. N. S.," Jersey Co., Ill. A patent may be taken, or at least they are taken, for inventions that have been in use for some years. The patent, when granted, is in force, and valid until upset by legal process, although it is one that might turn out to be void for want of some vital element in the application. Generally inventors deserve something for their labor, and although the invention may seem a simple thing, yet if it is worth making use of, it ought to be worth the cost of a trifling fee.

Have Patience!—"J. G. R.," and others. It is frequently impossible that we can procure illustrations of things requested, or even give replies to enquiries on the instant. Sometimes much study is required to answer what may seem a very simple request; and sometimes from necessity, a reply to a query, although in print, may lay over for a month. But, sooner or later, every inquiry or request is attended to.

Feeding Cotton-Seed.—"C.," The husk of cotton-seed is very hard and woody, and the lint which adheres to it is injurious to the stock, as it sometimes gathers in balls in the stomach, and often causes fatal inflammation. If fed at all, it should be thoroughly well boiled until soft, and then mashed and given with oat-chaff or cut hay. It is best to feed only the cake as it comes from the oil-mills free from the husks.

Remedy for Broken Wind in Horses.—"H. H. F.," Somerset Co., Pa. Broken wind consists of a violent breathing, with wheezing after severe exertion. It is caused by a permanent thickening of the lining membrane of the bronchial tubes, and is therefore incurable. All that can be done to ease it, is to feed lightly; to be careful against distending the stomach with water or food, and to avoid unusual exertion. Arsenic, in daily 5-grain doses, has been given with benefit. It is continued for several days, then suspended for a time, and afterwards repeated. This dose should only be given under the supervision of a competent surgeon.

Pigs that Won't Eat.—"J. C. J.," Bangor, Iowa. It is rarely that pigs will refuse corn-meal mush, bran, or middlings. A good method of preparing these feeds is as follows: Procure a large barrel, and throw a bushel of corn-meal, bran, and middlings in equal parts into it. Fill the barrel with water, throw in a few handfuls of salt, and stir the whole; leave it to ferment and become slightly sour, then feed. As soon as one barrel-ful is ready, prepare another, and so on, using them alternately. Milk or slops may be used with the water.

Any of these three books will be sent post-paid on receipt of the price.

Orders from the trade will be supplied in succession as received.

ORANGE JUDD COMPANY, 245 Broadway, New York.

Treatment for Chicken-Cholera.—"E. R.," Dayton, Ohio. As soon as fowls are seen to void a greasy liquid which smells badly, they should be given some condiment, as pepper, etc., which will soon set them right, unless their food, water, and roosting places are unclean and unwholesome. We find the "Imperial egg food," given twice a week, at the rate of a tablespoonful to a dozen fowls, to be an excellent preventive of disease, and to help in the production of eggs.

Pens at Paris.—As Joseph Gillott & Sons' pens are everywhere, they are, of course, at the "Exposition of '78" at Paris. While making a splendid display of their varied styles of pens, Messrs. Gillott have undertaken to illustrate Richelieu's well known saying, "The pen is mightier than the sword," by presenting a pen which, with its holder, is six feet long. Both pen and holder, which is of the choicest woods, are mentioned as remarkable works of art.

Various Kinds of Cultivators.—"J. M. B.," Elizabethtown, Ind. For the cultivation of vegetables, small fruits, and field crops grown in drills, we find Rue's hand-cultivator, which has several kinds of scrapers, teeth, and plows, for different operations, to be a very good one. It was fully described in the *American Agriculturist* of July, 1877. For cultivating potatoes, the writer uses a double mould-board plow, which earths up two rows upon one side at each passage, the horse walking between the rows.

Value of Potash.—"Z. M.," Queens Co., L. I. The cost of potash varies with the form in which it is sold. Sulphate of potash is higher in cost than the muriate, but still the sulphate is considered cheaper for root crops and fruits, on account of its action on the development of starch and sugar; while the muriate is just as good for grasses and grains. Unleached wood-ashes are worth, comparatively, 15 to 20 cts. per bushel.

Rye Among Corn. sown at the last hoeing, for plowing under the next spring, is a practice often adopted for the purpose of enriching the soil, and is a cheap and economical means to a desirable end. One and a half bushels of seed per acre are used.

Sowing Turnips.—"G. H. W.," Springfield, N. Y. To get a good crop of Swede turnips upon your acre of land, plow and harrow it fine; then with the plow open drills 27 inches apart; drop the 25 one-horse loads of manure in the drills, and cover it by plowing back the soil from each side. Smooth these ridges down by drawing a V shaped harrow lengthwise over them. With a hoe, open a shallow furrow for the seed, using about three pounds per acre. Then scatter along the furrow, upon both sides, about 300 pounds of fine bone-dust, or superphosphate of lime, and cover the seed with the mixed soil and fertilizer, burying the seed about one inch deep. When the plants appear above ground, thin them out to about a foot apart, keeping the rows free from weeds, and well cultivated.

Hay-tedders.—"P. & Sons," Boscobel, Wis. It will pay to use a hay-tedder where 40 acres of grass have to be cut. The cost is about \$50 or \$60, and hay can be cured with it in half the time required by hand.

Foul Sheath.—"J. W. S.," Henderson, Tenn.—This disease is generally the result of a poor condition, causing an increased and unhealthy exudation from the skin. Where this must necessarily accumulate, as in the sheath of a horse, its decomposition causes great irritation and discomfort, which affects the general health as well as the skin of the contained organ. The remedy is to examine the animal, using a soft cloth and a sponge, with warm, soapy water, to cleanse the parts. If the skin is injured, or any fungoid growths appear upon it, these should be touched with a solution of ten grains of sulphate of copper in one ounce of water, once a day until healed.

Clover in the South.—The report of the Georgia Agricultural Department is rarely without some valuable item of information. Recently we notice a statement to the effect that forty cases of hog cholera were averted, if not cured, by turning the animals on to a quarter of an acre of clover, to graze for one week. It has long been held that this disease springs mainly from mal-nutrition, and too much feeding on corn or other carbonaceous food. The fact that clover—a nitrogenous fodder—in this case averted the threatened disease is of great interest. The culture and use of clover in the South may through this knowledge be greatly extended.

Red Durhams.—"C. F. T.," Buckeys-town, Md. The so-called Durhams, or Shorthorns, properly speaking, are generally red, red and white in patches, roan, or white. The favorite color is a roan, which is

a mixture of red and white hairs, closely set together. That a Shorthorn is entirely red is not to be taken as an indication that there is Devon blood in the animal. A distinguishing mark of a Devon is the long, spreading horns; while a Shorthorn has short, neatly-curved horns. Red Shorthorns have a richer, purer red than the Devon.

Treatment of Heaves.—"T. S.," Pulaski Co., Ind. Heaves is often an hereditary or constitutional disease, depending upon a narrow and ill-formed chest; at other times it results from nerve weakness, and from indigestion, or it may be a result of all three combined. It is, therefore, seldom successfully treated by medicine. The course usually followed with success is to give moist, cut feed; but little corn, feeding crushed oats chiefly, in its place; to give with the feed four drams of sulphate of iron, with an equal quantity of ground gentian root, and to be careful not to overload the stomach with either food or water.

Sportsmen will find in "Hallock's American Club List and Sportsmen's Glossary" a complete list of the Angling, Athletic, Hunting, Kennel, Rifle, and Associations of similar character in this country; with forms of organization, rules of practice, and a glossary of technical terms; all very useful to members of such societies, and especially to those about to organize. For sale at this office; price 50 cents.

Green Rye for Pasture.—"J. W. A.," Lecmon, Mo. We have no reason to believe that green rye, when pastured, is injurious to hogs, or to any other stock. Some persons who have made complaints of it, we know to be fussy people who are in the habit of changing their minds frequently, and who are full of whims; some such complaints have been published in one or two papers, but we have no confidence in them.

Sugar Beets.—"A. B. O.," Clare Co., Mich. A dark, rich, sandy loam, will produce a good crop of sugar beets. The best variety for stock food is Lane's Imperial Beet, grown by Hon. Henry Lane, of Cornwall, Vt., which has yielded 48 tons per acre.

"One Hundred Architectural Designs," is a book from A. J. Bicknell & Co., which contains in 70 pages all these designs for country houses, city houses, stores, churches, stables, summer houses, interiors, etc., etc. Many of them have specifications and estimates of cost. The work is a collection of the best designs from a large number of works, and offers one desiring to build a rich variety to select from. Price, \$1, sent postpaid from this office.

Castor Bean Pomace.—"H. J. S.," Natick, Mass. For winter rye, or wheat, use about 400 lbs. per acre. All fine manures should be kept as near the surface as possible; would only harrow it in. When used for top-dressing, it should be mixed with loam or muck, allowing, say 300 lbs. of the pomace per acre. We would compost all such material with muck, stable-manure, or loam, that it might become thoroughly decomposed, and available for plant-food. If well covered with earth, it will thus keep uninjured for an indefinite period.

Milk from a Heifer.—"A Subscriber." It is not only possible, but easy, to bring a heifer, that has not yet had a calf, or that has not even been bred to a bull, into milk. All that is necessary is to excite the lacteal organs by permitting a calf to suck, or by the action of milking with the hands or fingers. We have seen two virgin heifers taking their place among the cows in a dairy, to be milked twice a day, and one of them gave 4 quarts a day at 14 months of age.

Improved Demand for Devon Cattle.—The New Herd Book.—H. M. Sessions, of South Wilbraham, Mass., writes us that the demand for Devons the past six months is greater than for the three years previous. The inquiries come from all parts of the country. Pedigrees for the 5th volume of the "Devon Herd Book" are now being received, and as soon as one thousand entries are made, the volume will be published. Mr. Sessions' herd now consists of 42 head, after having sold 20 in the past few months.

Yorkshire Swine Record.—"G. G. C.," Hamilton (?). There is no record of Yorkshire swine. Had you given the locality of your town, this reply would have been sent by postal card.

Red-water in a Calf.—"J. A. Q.," Closter, N. J. Raw flour in the drink is not wholesome for a calf; it irritates the intestines, and may be the cause of the red-water. In this case we would give two ounces of Epsom salts, repeating it the second day, and some thin, well boiled oat-meal gruel for drink. If the trouble is not removed, give a quarter of an ounce of hy-

posulphite of soda, daily, for a week, and give linseed-gruel in place of the oat-meal. Feed her no musty hay.

Indigestion in Sheep.—"J. H. H.," Northfield, Conn. An inclination to stretch itself, and stand with the fore and hind legs apart, is a symptom of indigestion in a sheep. The remedy is to give half a pint of raw linseed-oil, and a handful of salt to lick every day. When a sheep of a flock dies, it is best to examine the carcass, and discover the cause of the sickness, or at least be able to give some information upon which advice may be sought. The best book upon sheep raising is Stewart's "Shepherd's Manual," price \$1.50 by mail.

Treatment of Tanner's Refuse.—"C. L. M.," Fort Plain, N. Y., and "J. M. Y.," Saratoga Co., N. Y. Tanner's refuse, which consists of scraps of hide, hair, and lime, should be composted with stable-manure, or else spread upon the ground and lightly plowed in. When brought into contact with the moist warm soil, the hair rots very quickly. The whole requires heat, moisture, and time, to decompose. When using this matter we have mixed it with the manure in turning over the heap during the winter, and have found it ready for use in the spring for the corn crop.

Cheap Steamer for Cooking Feed.—"C. J. B.," Norfolk, Va. Descriptions with illustrations, of cheap cooking apparatus, are given in the *American Agriculturist* for November, 1874. These numbers can be had for 15 cents each.

To Preserve Harness from Rats.—"A. C.," Kane Co., Ill. The water-proof dressing, known as the "Tunyoap Water-tight," is said by its manufacturers to make harness that is dressed with it distasteful to rats and mice. As we have found on trial that the claims as to its water-proof qualities are justified, we infer the claim as to its protection of leather dressed with it, against vermin, is also well founded.

"Crackers for Horses."—"J. A. S." Had you given your Post-Office, instead of County, we should have long ago dropped a note saying that we know nothing of the matter beyond what was given.

To Hoist a Wagon-body.—"A Subscriber," Newton, N. J. The easiest way to hoist a wagon-body, is to have two strong hooks in the beam of the shed over the place for the wagon, and to suspend to each hook a block and tackle. Each end of the wagon box may be hooked to the tackle and hoisted, a few feet at a time, alternately, until it is out of the way. Or two pulleys may be hung to the beams, on swivels, and two ropes passed over these hooked to the ends of the wagon-box. The ropes may then be wound up by an axle and winch, fastened to the side of the shed, until the box is raised sufficiently.

Sheep Ticks.—"R. M. H.," Troy, N. Y. Where there is only a small flock, it is easy to hand-pick the ticks. To do this, the sheep is taken in front of the operator, who stoops over it and opens the wool; when a tick is seen, it is quickly snipped in two with a pair of short scissors; the eggs or pupæ are also killed in the same way. We have easily gone through with fifty sheep in this way, in half a day. It is not necessary to provide dipping apparatus for a small flock.

Oats and Peas.—"G. W. J.," Memphis, Tenn. The pea, in the mixed crop of oats and peas which is usually sown in the Northern States, is a true pea related to the garden pea, not the Stock or Cow-pea of the South, which is nearer a bean than a pea. The former pea climbs the oats, and is held up from the soil. The cow-pea, on the contrary, would not do this, but would spread over the ground.

Japanese Persimmon.—"J. B. B." We think that this would succeed in Kentucky, unless in an unusually exposed locality.

Value of Eggs.—As a hen may be expected to lay about 12 dozen of eggs, weighing 18 pounds, and to consume 60 pounds of corn in the year, it follows that for each pound of eggs, $\frac{2}{3}$ pounds of corn are used. There is no other animal product afforded so cheaply. Five pounds of corn costs now about 6 cents, and a dozen eggs, which are the product of that quantity of corn, are worth on an average during the year 20 cents. A brood of 10 chicks may be brought to a weight of 2 lbs. each upon a bushel of mixed corn and wheat, so that 20 lbs. of live weight can be produced from 60 lbs. of grain. There is then no more profitable farm stock than poultry.

Improvement of the Southern Levees.—"W. L. S.," Black Hawk, La., gives the fol-

lowing pertinent statement as to the loss caused by ineffective levees in the Southern States. "He lives on a plantation that would produce 500 to 600 bales of cotton if the levees were perfect, but in their present imperfect condition only 200 to 300 bales can be produced. If this loss occurs upon one plantation, what is the total loss in the whole of the river country? The question thus becomes one of more than individual importance; it is of great national interest.

"William Cullen Bryant, born Nov. 3d, 1794; died June 12th, 1878," was the simple inscription upon the coffin of one whose long life has been eulogized wherever the English language is spoken. Other journals have discussed his relations as poet, journalist, politician, etc. We record his death as one of our most intelligent horticulturists, and as one who, born amidst rural surroundings, never lost his love for country life, and who found in the forests and the flower themes for his most enduring poems. While he is claimed as a bright example in other pursuits, we record our high esteem of him as a lover of nature, whether manifested in the more artificial products of the garden and orchard, or in those of the woods and fields.

SHOW-BILLS for FAIRS.—Much of the success of Agricultural, as well as other Exhibitions, depends upon bringing them to the attention of the people attractively. A neat, speaking show-bill is effective for this. Officers of Agricultural Societies who may wish fine appropriate engravings for such bills, can obtain, at low rates, a selection from the largest and best assortment in this country, of Animals, Plants, Machinery, etc., etc., by addressing the publishers of the *American Agriculturist*. The back volumes of the paper will serve as a guide for selection.

Sowing Hungarian Grass.—"A. G. M." Shenandoah Co., Va. Hungarian grass is generally sown broadcast. The seed is very small, and half a bushel to three pecks per acre is sufficient. We know of no good reason why it may not be sown with a drill along with a sufficient quantity of artificial fertilizer, unless it may be that the operation would be longer and the seed deposited deeper than if sown broadcast. This crop should not be sown until the soil is thoroughly warm, and all danger of cold rains has passed. When sown broadcast, apply 200 lbs. per acre of some artificial fertilizer on the surface, after the seed has been sown upon the newly harrowed soil.

Price of Thorough-bred Cattle.—"S. K." Cattle of the pure breeds are valued at all ranges of prices from \$100 up to \$50,000, according to their character for fancy points, or the consideration in which their owners hold them. Fair useful cows can be purchased for \$200 to \$300, and bulls for \$100 to \$250.

Sowing Grass in Woodland.—"B. P. W." Raleigh, N. C. There are many opportunities of providing valuable pasture lots by seeding wood-lots down to grass. If the undergrowth and rubbish are removed, and the ground lightly broken up with the plow and harrow, it may be seeded without difficulty. Orchard grass, and Kentucky blue-grass, thrive best under timber. A bushel of each may be sown per acre.

Wheat in South Australia.—The following statistics of the wheat-crop in South Australia, will not only give interesting information regarding the agriculture of this British Colony, but will also tend to show that the low average of the American crop is even surpassed in lowness by that of Australia. The figures for the past four crops are as follows:

Year.	Acres in Wheat.	Produce bush.	Average per Acre.	Price per bush.
1873-4	784,784	6,178,816	7.62/100 bus.	\$1.39
1874-5	839,633	9,869,963	11.46/100 "	1.13
1875-6	898,830	10,739,834	11.97/100 "	1.25
1876-7	1,083,732	5,857,569	5.24/100 "	1.50

The Australian farmer can by no means rejoice over his American brother; on the contrary, the latter may congratulate himself that he is not the only, nor the worst sufferer, from small wheat-crops.

Bullet in Horse's Thigh.—"W. L." Crockett, Tex. To effect a cure of a wound caused by a rifle shot, the ball must be extracted, which can only be done by a surgeon. You had best call the ablest one in your neighborhood. Cast and confine the horse for him, and let him operate as if the patient were a man.

Artesian Wells.—"J. L. B." Grant Co., W. Va. No one can say if an Artesian well can be procured except by testing the question by boring for the water. On examination of the locality, a competent geologist might give an opinion as to the probability of success, but no certain promise. For success, one must

strike a subterranean current which has its source above the level of the mouth of the well. To do this is not always possible, and rarely probable. The Driven Well is an excellent substitute for the Artesian, and will work in any locality where it can be put in without excavating boulders or ledges.

Production of the Best Cows.—"H." The best cows sold in the New York City markets, and quoted at the highest prices, viz., from \$60 to \$80, will give from 20 to 22 quarts daily.

Sanford Corn.—"R. D. B." Bedford Co., Va. We can not say where the Sanford corn, which is a kind very useful for fodder, can be procured. There have been many inquiries for it this season that we were unable to reply to, for the reason that those who have it neglected to advertise it.

To Rid a Barn of Rats.—"A Subscriber." The method is as follows: Procure several empty barrels, and put a quantity of bran or grain in them, and leave them for the rats to feed in without disturbance for a few days. Then remove the bran, and half fill the barrels with water, covering the surface with bran. The rats will go into the barrels without hesitation, and many will be caught. To prevent the increase of rats, avoid having any hiding places, leaving the floors open to the entrance of cats, raise all the sheds and buildings above ground on posts, and have no wooden floors.

Nuts and Nubbins.

The Virginia bell-punch is not a thermometer—it is more like a bar-room-meter.

It is said that sliding down hill was the direct cause of over six hundred deaths during the last winter. Moral—Always slide up hill.

Statistics show that the number of idiots is increasing; and yet some newspapers continue to make war on quack doctors. What is a quack doctor for but to kill off the fools?

A young man sent 60 cts. to a firm in Michigan that advertised a receipt to prevent bad dreams. He received a slip of paper, on which was written: "Don't go to sleep."

"I say, Jim, if five and a half rods make a perch, how many will make a pickerel?"—"You just tell me, first, if two hogheads make a pipe, how many will make a meerschaum?"

The manufacture of paper from wood has reached perfection in Canada. The superintendent of a mill up there says a tree is cut down and shoved into one end of the mill, and five minutes later there is a neighbor at the other end to borrow the paper.

Franky L. was told to watch a cow feeding on the Common. After a while his mother went out to see if her darling wanted relief, but the cow was nowhere in sight. "Why, Franky!" said she, "I thought I told you to watch the cow."—"And so I did, so long as she was in sight."

We have a bell in our private office. It is used to call one of our boys with. At least that is the popular legend connected with the article. When we want one of the boys we ring the bell, and then go out in the back office and hunt him up and tell him of the fact. It always pleases him to learn that we have been ringing.

A man saw a ghost, while walking along a lonely highway, at midnight. The ghost stood exactly in the middle of the road, and the wayfarer, deciding to investigate, poked at it with his umbrella. The next instant he was knocked twenty feet into a mud-hole. Moral—Never poke at a large white mule when its back is turned.

A Connecticut editor shows his familiarity with agriculture in the following: "T is wheat to n-oat the progress of the approach of spring. Onion-cer hills and meadows nature is bean arrayed in all herb beauty. The farmer manifests corn cider-apple zeal in his effort to secure early field crops, while the gardens, with t-hay-r-radish-ional work, are being carefully attended to."

A sharp trick for custom was played by two San Francisco hackmen the other night. As a theater audience was departing they stationed themselves at the door with large and open umbrellas. Without stopping to investigate, those who had umbrellas put them up, while those who had not put handkerchiefs over their heads and broke for the carriages, and the enterprising Jebus drove off with full fares.

The Need of Pronouncing Distinctly.—"Guest at Hotel."—I want to get up at eight o'clock.—"Hotel Clerk."—Want what, sir?—"Guest (emphatically)."—I want to get up at eight o'clock.—"Hotel Clerk."—We haven't any such thing in the house, sir!—"Guest (angrily)."—What do you mean, sir?—"Clerk."—I mean that we haven't any such thing in the house as a "potato-clock!"

WARING'S Books FOR Farmers.

DRAINING FOR PROFIT, AND DRAINING FOR HEALTH.

By GEO. E. WARING, JR.,
Engineer of the Drainage of Central Park, New York.

CONTENTS.
LAND TO BE DRAINED; HOW DRAINS ACT; HOW TO MAKE DRAINS; HOW TO TAKE CARE OF DRAINS; WHAT DRAINING COSTS; WILL IT PAY? HOW TO MAKE TILES; RECLAIMING SALT MARSHES; HOUSE AND TOWN DRAINAGE.

He (the author) describes the action of draining upon the soil, the construction of single drains and systems of drains, the cost and the profit of thorough drainage, the making of tiles, and the reclaiming of salt marshes, treats sensibly of malarial diseases, and closes with a chapter which should be widely read, on house drainage and town sewerage in their relations to the public health.

A Book that ought to be in the hands of every Farmer.
Price, Post-paid, \$1.50.

ELEMENTS OF AGRICULTURE. A BOOK FOR YOUNG FARMERS.

By GEO. E. WARING, JR.

CAREFULLY REVISED.

CONTENTS:—THE PLANT; SOIL; MANURES; MECHANICAL CULTIVATION; ANALYSIS.

The foregoing subjects are all discussed in plain and simple language, that any farmer's boy may understand. The book is written by a successful *practical farmer*, and is full of information, good advice, and sound doctrine.
Price, Post-paid, \$1.00.

THE SANITARY CONDITION OF City and Country Dwelling Houses.

By GEORGE E. WARING, JR.

CONTENTS: The Sanitary Condition of Country Dwelling Houses. The Sanitary Condition of City Dwelling Houses. Flinnder's System for the Ventilation of Soil Pipes. Correspondence.
Price, post-paid, 50 cents.

Either of the above books sent post-paid on receipt of price, by

ORANGE JUDD COMPANY, 245 Broadway, N. Y.

GARDNER'S RAILWAY PITCHING APPARATUS.

Consisting of Carrier, Grappling Fork, Pulleys, and Hooks. For unloading Hay, Grain, Beans, Corn Stalks, loose or in bundles, etc. Can be used in any barn. Also, Improved Stacking Apparatus. Send for Circular, and get valuable information.

E. V. R. GARDNER & CO.,
Johnson's, Orange Co., N. Y.

Use the Anti-Friction Hay-Carrier,

For elevating and conveying Hay, Grain, etc., in barn, bar-rack, shed, or field. It elevates perpendicularly and conveys horizontally any desired distance. No trouble about getting over high beams and to the end of deep mows, or to the top of high stacks. **Thousands are now in use.** Five tons have been stacked and the frame moved in 45 consecutive minutes. Fifty tons have been stacked in a single day with this Frame and Carrier. Send for Circular "2" to U. S. WIND ENGINE & PUMP CO., Batavia, Ill.

Fitzhugh's Am. Hay-Elevator. The greatest labor-saving machine in use. Easily put up and operated. It will take one ton of hay from the wagon and carry it back 100 feet in 15 minutes. Only occupies 14 in. of space in peak of barn. It is very durable and cheap. Price \$12.00. Send for descriptive catalogue. J. R. FITZHUGH, Mr. and Pat., 1708 Barker St., Philadelphia, Penn. Branch Office 55 Beekman St., N. Y.

THE SILVER & DEMING Endless Chain Horse Powers,

for one, two, and three horses, are the best made. They have steel track rods, wrought iron links, and for strength and durability are unsurpassed.

Our improved Governor regulates the speed perfectly. We also manufacture Drag and Circular Sawing Machines.
Silver & Deming Mfg. Co., SALEM, OHIO.
Send for circular.

EDWARD HARRISON, New Haven, Conn.
(William A. Fokett, Administrator.)

Big Giant Corn Mill, Every Man His Own Miller.

The only Mill that will grind Corn with Shuck on without extra expense. The only Mill grinding Corn and Cob successfully that will grind Shelled Corn fine enough for family use. Grinds twice as fast as any other Mill of same size and price.

MANUFACTURED BY
J. A. FIELD, SON & CO.,
922 N. 2nd St., St. Louis.

WILLIAM CROZIER has much pleasure in calling the attention of Cow-keepers, Farmers, and Dairywomen to the **NEW SELF-MILKING APPARATUS.** This Apparatus or Cow Milker, has been tested by a large number of practical Agriculturists, Dairywomen, &c.; and, without exception, merited high encomiums and commendations, for its adaptability and wonderful rapidity in the Milking of Cows. It is considered one of the most invaluable and useful Machines yet invented.

Amongst its many advantages are—

1st—It is **SELF-ACTING**, easy of application; and can be used by any person, however ignorant of Milking.

2nd—It will Milk any Cow in **FOUR Minutes** effectually, and its use is more agreeable to the Cow than Hand-Milking.

3rd—It is a great boon in the case of Sore or Corded Teats.

4th—Its Usefulness, Simplicity, Saving of Time, Cleanliness, Durability, and Cheapness, prove it to be a most important and necessary adjunct to a Dairy, and it has only to become better known to be universally used.

Sent free on receipt of Post Office order for \$5.

Printed Instructions accompany each Machine.

All infringements will be vigorously prosecuted.

MILK TUBES.

COW-KEEPERS should not be without one of these, as they are invaluable for sore or Corded Teats.

PRICE \$1.00 each.

WM. CROZIER, Northport, L. I., N. Y.

Automatic Cow-Milker.

I have the best and simplest milker in the world, made all of pure silver. It is easily kept clean, and has no flexible or rubber tubes to sour and spoil the milk in warm weather. It is easily applied, and can be seen while milking that every teat is flowing.

Will milk sore or short teats, or kicker.

Fractious cows become very gentle by the use of my milker. It is the cheapest, best, and only perfect milker.

It never gets out of order—never wears out.

It will milk any cow very quick.

Price \$3.00 per set; two sets, \$5.00. Single Tubes, 75 cents. Full directions. Agents wanted for every County in each State.

WM. F. ELY, P. O. Box 226,

Madison, Morris Co., N. J.

The Self-Acting Cow Milker,

Pat'd May 28th, 1873, is just the thing every one needs who keeps cows. Any child can use it, while the men are at work in the field. Sent to any part of the U. S. on receipt of \$2.00. Send for descriptive illustrated pamphlet, containing internal views of a cow's teats and bag, dissected by Drs. White and Wilson, of this city, and testimonials from Vet. Surgeons and Farmers, who have tested the milker for over six mos. Agents wanted for U. S., South America, and Australia.

Sale of Imported Jersey Cattle, AT CINCINNATI, OHIO.

ALFRED M. HERKNES & Co. Sole Agents for Mr. Edward P. P. Fowler, of Jersey and Southampton, England, will sell at auction, without reserve, in the City of Cincinnati, O., early in July,

TWELVE PURE BRED JERSEY HEIFERS, direct from the Channel Islands. Eligible to entry in the American Jersey Cattle Club's Herd Register. Catalogues, giving date and place of the sale, can be had on application to Herkness Bazaar, North and Sansom Streets, Philadelphia, Pa.

THOROUGHbred JERSEY BULLS.

The time for breeders and dairy farmers to purchase is the present. I offer for sale 12 **JERSEY BULLS**, from 11 months to 26 months old. All were sired by my bulls "Pierot 2d" or "Pierot 7th." No better sires exist. All are from cows of large butter yield. All have beautiful colored coats and skins, and several are solid fawn, with black points. All are able to serve cows at once. Five of them are subject to entry in the A. J. C. C. Register. Of course they must be gilt-edged. Lowest price, \$100; highest price, \$200.

THOMAS FITCH, New London, Conn.

BOYS
here's a for-
tune for you.

It Pays for 2 Days.
Itself in

"I made \$60
first month."

VIEW OF LATHE AND SAW.

A \$10 SCROLL AND JIG SAW FOR \$3.

In our new "My Companion" Jig Saw, we offer a prize to the Boys of America. You can make \$5 per week working evenings, and learn a trade that will always give you good wages. The New Improved My Companion Jig Saw is as good and will do finer work than any \$15 or \$20 Saw in the world. It is not a toy, it is a practical machine, and used by both professional and amateur workmen. Description.—Length of Arms, 21 inches; Length of Arm for work, 18 inches; Height of Table, 31 inches; Diameter of Balance Wheel, 61-2 inches; Diameter of Drive Wheel, 12 inches; length of Stroke, 13-4; Number of Strokes of Saw per minute, from 800 to 1,000. A competent carpenter says, "I cannot make this saw for \$10; I should not get paid for my time alone." We make them by the 10,000; make each part with special and expensive machinery, which cuts out and finishes with great rapidity, each part fitting exactly where it belongs, and there is no waste of material or time. A SINGLE MACHINE COULD NOT BE MADE FOR \$15. The frames are of best oak and ash, with iron wheels, blocks, braces, and connections, and steel bearings. Each one warranted for ten years; every one adjusted and tried before sold. Directions sent for putting together which can be done in ten minutes. Every boy is delighted with bracket sawing; it pays them good wages, and their work commands a ready sale. Our saw completely fills the long felt want for a foot power saw that will do the best work, AND BE WITHIN THE REACH OF THE POOREST BOY. We make but very little on a single saw, but we mean that every boy in America shall have one. Both the press and mechanics flatteringly endorse our saw. It is an UNPRECEDENTED BARGAIN. Messrs. Perry, Mason, & Co., editors of the *Youth's Companion*, say, "It will saw as fast, DO AS BEAUTIFUL WORK, AND CUT OUT AS LARGE WORK AS ANY \$10 MACHINE IN THE WORLD. It takes apart and packs in a very small space, (only 36 inches by 13 inches by 4 inches,) and weighs only 25 pounds, and sent to any address on receipt of only \$3.00 or with a powerful drilling attachment and full set of drills, only \$3.50; or with the drill and a powerful Circular Saw and a large and complete Turning Lathe (with a full set of Turning Tools,) only \$5.00; making a complete work-shop that will do first class work, and that could not be bought equally as good elsewhere for \$25. With each saw we give over fifty original Designs and Patterns, four Saw Blades, and four illustrated lessons for beginners. The saw can be sent C. O. D., to any point east of Ohio on receipt of \$1.50 to guarantee charges, which is deducted from the bill; but when the cash accompanies the order we give free extra saws and our 50 ct. price sheet of Designs. If it is not all we claim and you are not satisfied, we will refund your money. Address all orders for the New Improved My Companion Scroll Saw to the Turner Manufacturing Co., 93 Water St., Boston, Mass.

THE COMPANION SCROLL SAW.

I Offer the following for Sale,
from my own importation and prize herd of *Ayrshire*, 4 yearling Bulls, 3 Bull Calves, and 16 *Ayrshire* Cow Calves, a few yearling *Southdown* Rams and *Ram* Lambs from imported ewes and ram; 8 young *Shepherd Collie* Pups.

Copies of the Catalogue will be sent to the trade on application. They will be mailed to individuals on the receipt of two three-cent postage stamps.

ORANGE JUDD COMPANY,
245 Broadway, N. Y.

The Western Grasshoppers.

A Valuable Work by Prof. Riley.

THE LOCUST PLAGUE IN THE UNITED STATES:

Being more particularly a treatise on the Rocky Mountain Locust, or so-called Grasshopper, as it occurs east of the Rocky Mountains. With practical recommendations for its destruction. By Prof. Charles V. Riley, State Entomologist of Missouri; Chief of the U. S. Entomological Commission; Author of "Potato Pests," etc. With 45 illustrations.
Price, Post-paid, \$1.25.

Play and Profit in my Garden.

By E. P. ROE,

Author of "Barriers Burned Away," etc.

NOTICES BY THE PRESS.

The author takes us to his garden on the rocky hill-sides in the vicinity of West Point, and shows us how out of it, after four years' experience, he evoked a profit of \$1,000, and this while carrying on pastoral and literary labors. It is very rare that so much literary taste and skill are united to so much agricultural experience and practical good sense. —*Harper's Magazine.*

This book is as poetical as it is practical. Still he is no dreamer. He goes into every essential detail with as much minuteness and precision as if he were writing a manual for the practical farmer. Indeed few works professedly devoted to agriculture give more sound and valuable information on the secret of winning golden harvests from the soil than this brief idyllic sketch. —*N. Y. Tribune.*

Price, Post-paid - - - - \$1.50

REVISED EDITION.

The American Standard of Excellence,

As revised by the American Poultry Association at their Convention held in Chicago, giving a complete description of all the recognized varieties of thoroughbred fowl. This edition contains the latest appendix, and should be in the hands of every breeder of choice poultry.
Price, post-paid, \$1.00.

BUTTER AND BUTTER-MAKING,

With the best Methods for Producing and Marketing it. By WILLIS P. HAZARD, President of the Chadd's Ford Farmers' Club, author of the "Jersey, Alderney, and Guernsey Cow," etc. Illustrated. 12mo. Paper cover. Price, post-paid, 25 cents.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD COMPANY,
245 BROADWAY, NEW YORK.

A Trochar for Cattle-Men.

In June of 1872 we gave illustrations of a Trochar and Cannula to be used in ringing a bull, and on page 13 (January) and page 97 (March) of the *American Agriculturist* for 1873 (copies of which may be got from this office for 15 cents each) we described the use of this apparatus in relieving hoven in cattle. These articles have brought out a large demand for Trochars, and failing to find just the right kind among the makers of surgical implements, we have induced an establishment to undertake their manufacture. We give herewith a small engraving of the Trochar. These articles are now in the trade, and may be had of most dealers in agricultural implements. Those who can not get them from dealers can receive them from this office, prepaid, for \$1.00.
ORANGE JUDD COMPANY, 245 Broadway, N. Y.

Read What is Said Below About Books for Farmers.

In response to a request made of one whose thorough and practical knowledge on all matters pertaining to the Farm, Garden, and Household is so fully conceded that his opinions could not fail to secure attention and command respect were we permitted to give his name, we have received the following as his judgment concerning some of the works on our Catalogue of Books for Farmers.

Any of these Books will be forwarded, post-paid, to any address in the United States or Territories, on receipt of the price, by Orange Judd Company, 245 Broadway, New York.

For a Farmer's Home Library.

The New American Farm Book.

By R. L. and L. F. ALLEN.
Price \$2.50.

This is the best American work upon general farm management. It treats of the leading crops, buildings, draining, etc., and includes sufficient about animals of different kinds to meet the wants of most farmers.

Farm Implements and Machinery.

By JOHN J. THOMAS.
Price \$1.50.

Most farming operations are accomplished by force, applied through implements and machines, and a farmer should understand mechanics, at least sufficiently to apply force most economically. In this work the fundamental principles are clearly taught, and their application illustrated.

American Weeds and Useful Plants.

By DR. WM. DARLINGTON.
Price \$1.75.

For the farmer who wishes to know something about the weeds upon his farm, as well as useful cultivated and wild plants, this will answer better than a general treatise on botany.

How Crops Grow, (price \$2.00), and How Crops Feed, (price \$2.00.)

By Prof. SAM'L W. JOHNSON.

If I could have but two books in such a library it would be these, as I consider them the most important contributions to agricultural literature of modern times. They contain all of vegetable physiology and agricultural chemistry that any except special students need, and nowhere is there so much of agricultural condensed in so small a space. As works of reference they are indispensable.

Country and Suburb- an Homes.

By D. T. ATWOOD.
Price \$1.50.

Such a library should have some work on domestic architecture. Most works upon the subject are costly on account of the designs. This is one of the best works, at a moderate price, and contains, with other matter, the method of building with concrete.

The Fruit Garden.

By P. BARRY. Price \$2.50.

After the farm crops, fruit is of the most importance. No work covers the whole subject so completely as this.

Gardening for Profit.

By PETER HENDERSON.
Price \$1.50.

Farmers near cities often make more from garden crops than from farm crops. This is the best work on market gardening, and will serve for the family garden also.

Gardening for the South.

By WM. N. WHITE.
Price \$2.00.

An excellent garden book, and in the libraries for Southern farmers might be substituted for Henderson's, but it would be well to have both.

The New Book of Flowers.

By JOSEPH BRECK.
Price \$1.75.

I do not know of any book upon out-door flower gardening that on the whole is so good as this. Its teachings are sound, and style pleasing.

Mysteries of Bee- Keeping.

By M. QUINBY. Price \$1.50.

Practical Poultry- Keeper.

By L. WRIGHT. Price \$2.00.

Swine Husbandry.

By F. D. CORBURN.
Price \$1.75.

The Pig.

By JOSEPH HARRIS.
Price \$1.50.

Bees, Poultry, and Pigs are often made subjects of especial care by small farmers, and separate treatises on these are more likely to be asked for in a library like this than those upon the larger animals. Each of these stands in the front rank of books in its line.

Draining for Profit.

By GEO. E. WARING, JR.
Price \$1.50.

So in farm operations the work of Draining, important as it is in many cases, is not likely to be treated sufficiently in detail in general works.

Irrigation.

By HENRY STEWART.
Price \$1.50.

A most timely book, for inquiries are numerous upon this subject of "Irrigation for the Farm, Garden, and Orchard." This is plainly written and copiously illustrated; is thoroughly practical, and sufficiently suggestive to meet almost any possible case in which water may be used for the benefit of the crops. It is, in short, a practical manual of irrigation, which will be useful in a wide diversity of instances.

The Shepherd's Manual.

By HENRY STEWART.
Price \$1.50.

This work is regarded by competent judges as the most valuable production in the department of husbandry of which it treats. It is very fully illustrated, and is designed to be a help to every sheep owner, whether his flock be large or small.

Potato Pests.

By PROF. C. V. RILEY.
Price, paper covers, 50 cts.;
cloth, 75 cts.

No farmer can afford to be without this little book. It gives the most complete account of the Colorado Beetle anywhere to be found, and includes all the latest discoveries, as to the habits of the insect and the various means for its destruction. It is well illustrated, and exhibits in a map the spread of the insect since it left its native home.

Tim Bunker Papers.

Price \$1.50.

As all the other works are matters of fact, it may be well to have a little pleasure. This conveys much sound teaching on rural economy in a quaint style, and it is sometimes policy to sugar-coat your pill.

Books for a Larger Library.

Besides all the works in the foregoing list, I would add the following:

- American Cattle.** L. F. ALLEN. \$2.50.
- Randall's Sheep Husbandry.** \$1.50.
- Hints to Horse Keepers.** H. W. HERBERT. \$1.75.
- American Cattle Doctor.** 12mo. G. H. DADD. \$1.50.
- Modern Horse Doctor.** 12mo. G. H. DADD. \$1.50.
- Insects Injurious to Vegetation.** DR. HARRIS. \$4.00.
- Small Fruit Culturist.** A. S. FULLER. \$1.50.
- Draining for Profit and Draining for Health.** G. E. WARING, JR. \$1.50.
- Cranberry Culture.** J. J. WHITE. \$1.25.
- Grape Culturist.** A. S. FULLER. \$1.50.
- An Egg Farm.** STODDARD. Paper 50c.; cloth 75c.
- Hops.** 30 cts. **Flax.** 30 cts. **Tobacco.** 25 cts. **Onion.** 20 cts. Essays.
- Boussingault's Rural Economy.** \$1.60.
- Play and Profit in My Garden.** ROE. \$1.50.
- Landscape Gardening.** DOWNING. \$6.50.
- Gardening for Pleasure.** HENDERSON. \$1.50.
- The Book of Evergreens.** J. HOOPES. \$3.
- Farm Gardening & Seed Growing.** BRILL. \$1.
- Hunter and Trapper.** H. THRASHER. \$1.
- The Market Assistant.** DEVOE. \$2.50.
- Hedges and Evergreens.** WARDER. \$1.50.
- Pear Culture.** P. T. QUINN. \$1.
- Money in the Garden.** QUINN. \$1.50.
- Peach Culture.** FULTON. \$1.50.
- Broom-Corn and Brooms.** Pap. 50c. Cl. 75c.
- Caldwell's Agricultural Chemical Analysis.** \$2.00.
- Geyelin's Poultry Breeding.** \$1.25.
- Gregory on Cabbages.** 30c.
- Johnson's Agricultural Chemistry.** \$1.75.
- My Vineyard at Lakeview.** \$1.25.
- Nichol's Chemistry of the Farm and Sea.** \$1.25.
- Parsons on the Rose.** \$1.50.

VALUABLE ARCHITECTURAL BOOKS

Atwood's Country and Suburban Houses.

This work is finely illustrated with about one hundred and fifty engravings, and gives instruction upon all points, from the selecting of a place to build, to the perfect completion of the house. By D. T. Atwood, Architect. Cloth, 12mo. Post-paid, \$1.50.

Hussey's Home Building, From New York to San Francisco.

It is EXTENSIVELY ILLUSTRATED, containing 42 Plates of Perspectives, with Plans of 45 Original Buildings, of as many classes, and their cost; and an INVALUABLE TABLE of materials, labor, and prices, at about 400 cities, towns, and hamlets, from the Atlantic to the Pacific. Also, complete and ELABORATE SPECIFICATIONS of materials and labor; merchandise, and where it may be procured. It also contains original descriptions and valuable statistics for 1876 of over 250 Cities and Towns. By E. C. Hussey, Architect, author of Hussey's National Cottage Architecture, &c. Post-paid, \$5.00.

Palliser's American Cottage Houses.

Entirely New Designs for Country, Suburban, and Village Cottages; Villas and Houses. The authors of this work have endeavored to combine good taste with practical, convenient plans, and sound construction. Their aim is to get the best effect in the simplest, most common-sense, and least expensive manner.

The designs are entirely new and attractive, and are accompanied with plans, elevations, specifications, details, working scales, and estimated cost of construction. The estimates run from \$350 to \$3,500, so that it may be called a book for all. Post-paid, \$5.00.

JUST PUBLISHED.

Bicknell's Specimen Book of 100 Archi- tectural Designs.

This work shows a great variety of Plans, Elevations, and Views, of Model, Modern Homes, from Designs of the foremost architects in the country.

It is a very desirable book for builders, and all who contemplate building or remodeling. Handsomely bound in cloth, 8vo. Post-paid, \$1.00.

Allen's Rural Architecture.

Practical Directions and Suggestions for Construction of convenient Farm-Houses, Cottages, and Out-Buildings, including Barns, Stables, Sheds, Carriage and Wagon-Houses, Work-Shops, Wood-Houses, Ash and Smoke-Houses, Ice-Houses, Poultry and Bee-Houses, Dove-Cotes, etc., together with directions for the Gardens and Grounds; useful and ornamental Domestic Animals, etc. By Hon. Lewis F. Allen, Editor of "American Herd-Book," "New American Farm Book," etc. Cloth, 12mo. Post-paid, \$1.50.

Lakey's Village and Country Houses.

Or, Cheap Houses for All Classes, comprising eighty-four pages of designs. The object, in almost every instance of these designs, has been to secure as large an amount of space and comfort as was possible with the least expenditure of money, without neglecting the exterior features of each building. Royal Quarto. Post-paid, \$5.00.

Leuchars' How to Build Hot-Houses,

Green-Houses, Graperies, etc., etc., and how to Ventilate them. Illustrated with numerous Engravings. This is the only work published in this country, specially devoted to this subject. By Robert B. Leuchars, Garden Architect. Cloth, 12mo. Post-paid, \$1.50.

Either of the above books sent post-paid on receipt of price by
ORANGE JUDD CO., 245 Broadway, New York.

THE PRACTICAL POULTRY KEEPER.

A COMPLETE AND STANDARD GUIDE TO THE
MANAGEMENT OF POULTRY,
FOR DOMESTIC USE, THE MARKETS, OR
EXHIBITION.

Beautifully Illustrated.

By L. WRIGHT.

NOTICES BY THE PRESS.

This book is a valuable manual for everybody who feeds chickens or sells eggs. It suits at once the plain poultryer who must make the business pay, and the chicken fancier whose taste is for gay plumage, and strange, bright birds. The most valuable portion is the first section, extending through fifty-five pages. These were written with the intention of producing a manual so plain, minute, and practical, that any one could, by using it as a guide, with no previous experience with poultry, become at once successful in producing eggs, young chickens, and fat fowls for market. The author has not missed his aim. The middle parts of Mr. Wright's Manual are taken up with minute directions for making show fowls for Fairs, a nice discussion of the good and bad points of the different breeds, and a brief sketch of such fancy stock as peafowl, pheasants, and water-fowl. Then follows a section on artificial hatching, and another, worth special attention, on large poultry yards. A study of Mr. Wright's book will convince any farmer's wife that all she needs is to give a half hour each day, of intelligent and sagacious attention to her poultry, in order to obtain from them, not tape, and knitting needles, and buttons, and nutmegs merely, but the family supplies of sugar, shoes, and cloth. *New York Tribune.*

It is the most complete and valuable work on the matters of which it treats yet published. It will be found a plain and sufficient guide to any one in any circumstances likely to occur, and is illustrated with elegant engravings of many breeds of fowls. *Farmers' Cabinet.*

This is a reprint, with numerous wood engravings, of an English book, the object of which is to convey in plain language a great deal of practical information about the breeding and management of poultry, whether for domestic use, the markets, or exhibition. The book is eminently practical, and we recommend it to farmers and others interested in breeding and selling poultry. *Philadelphia Press.*

It is a handsome volume, brought out in the best style, and enriched with nearly fifty illustrations. It is evidently the fruit of a thorough, practical experience and knowledge of fowls, and will be found a plain and sufficient guide in all the practical details of poultry management as a profitable business. *United Presbyterian.*

The subject is treated fully and ably by an experienced hand, and the volume will doubtless find a large sale among the growing class of poultry fanciers. It is embellished with numerous illustrative engravings. *New York Observer.*

The author has called to his aid all who were experienced in the subject whereof he writes, and the consequence is a volume of more than ordinary thoroughness and exhaustiveness. *Rochester Democrat.*

The book is a complete and standard guide to the management of poultry for domestic use, the market, and for exhibition. *Watchman and Reflector.*

PRICE, POST-PAID, \$2.00.

Potato Pests.

Being an Illustrated Account of the
Colorado Potato-beetle

AND THE OTHER

Insect Foes of the Potato
IN NORTH AMERICA.

With Suggestions for their Repression
and Methods for their Destruction.

BY

CHARLES V. RILEY, M. A., PH. D.

(STATE ENTOMOLOGIST OF MISSOURI.)

FINELY ILLUSTRATED.

TABLE OF CONTENTS.

THE COLORADO POTATO-BEETLE.

Its Past History.—The Insect's Native Home.—Rate at which it traveled.—How it traveled.—It spreads but does not travel in the sense of leaving one District for another.—Area invaded by it.—Causes which limit its Spread.—How it affected the Price of Potatoes.—The Modification it has undergone.—Its Natural History.—Its Poisonous Qualities.—Its Food Plants.—The Beetle eats as well as the Larva.—Its Natural Enemies.—Remedies.—The Use of Paris Green.—Bogus Experiments.—Alarm about the Insect Abroad.—Nomenclature.—The Bogus Colorado Potato-beetle.

OTHER INSECT FOES OF THE POTATO.

THE STALK-BORER.—THE POTATO STALK-WEEVIL.—THE POTATO OR TOMATO-WORM.—BLISTER-BEETLES. The Striped Blister-beetle. The Ash-gray Blister-beetle. The Black-rat Blister-beetle. The Black Blister-beetle. The Margined Blister-beetle.—THE THREE-LINED POTATO-BEETLE.—THE CUCUMBER FLEA-BEETLE.—THE CLUBBED TORTOISE-BEETLE. Price, Post-paid, paper covers, 50 cts.; cloth, 75 cts.

The Farm-Yard Club of Jotham.

An Account of the Families and
Farms of that Famous Town.

By GEORGE B. LORING.

NOTICES BY THE PRESS.

The Farm-Yard Club of Jotham, an Account of the Families and Farms of that Famous Town, so happily combines the information which both the amateur and the professional farmer need, with the charms of individual experience and characterization, that it will please a great variety of tastes. The number and excellence of the illustrations deserve special mention, the designs being tastefully conceived and skillfully executed, and having, moreover, a peculiar appropriateness.—*Globe*, Boston, Mass.

Dr. Loring has given us a book which is at once cyclopedic in its information, entertaining for its wit and humor, and interesting as a story, for the bright thread of real life and love that runs through it.—*Golden Rule*.

Octavo, 603 pages, with 70 Illustrations of Characters, Country Scenes, Farm Animals, and Implements, by Champney, Rose, Lathrop, Forbes, and others. Price, post-paid, \$3.50.

THE

"Model Piano."

PRICE \$150 to \$200.

The "MODEL" is a beautiful little Upright or Cottage piano; it is manufactured from the best materials that can be procured; the workmanship is excellent, and its durability is guaranteed; it is small, light, and occupies but little room, is easily transported, and above all the "MODEL" is sold at about one-third the price that is usually paid for any other reliable piano. For the above reasons, it is very suitable for people of moderate means, and those living in small houses; but it is especially adapted for beginners, and on account of its low price, commends itself to every parent, because it possesses all the principal features of the finest piano, and has none of the numerous disadvantages of the reed organ.

For full particulars write for illustrated pamphlet, and state where you saw this notice.

THE GLOBE NAIL. THE BEST HORSE SHOE NAIL EVER MADE.

About ten years ago the GLOBE NAIL COMPANY of Boston, put on the market the first pointed, polished and finished Horse Shoe Nails ready for driving. Previous to that time all Horse Shoe Nails were pointed, and most of them made, by the shoers in their own shops at the rate of but six pounds per day.

The Globe Nail was at once found to be much cheaper and better than any then in use. It soon became so popular that all manufacturers of Horse Shoe Nails were compelled to make their Nails to resemble the Globe. For the last ten years it has been the model. Each year the Nail has been greatly improved in quality, and to such a point have we educated the shoers that now they will hardly use a nail unless it is absolutely perfect.

At the Centennial Exposition in Philadelphia, we were awarded the Medal and the following report, far stronger than that given upon any other Nail:

INTERNATIONAL EXHIBITION, 1876.
U. S. CENTENNIAL COMMISSION.

[BUREAU OF AWARDS.]

PHILADELPHIA, June 22, 1876.
No. 239, Globe Nail Co., Boston, Mass.:

Horse Shoe Nails, Pointed, Polished, and Finished. The uniformity in size, smoothness of finish, hardness and tenacity of the iron, closeness of fibre, and excellence of the head and point, the tensile strength of body, and riveting properties of these Nails, unite in making them of the very highest class of manufactures.

Recommended for an Award of Merit.
DANIEL STEINMETZ, Phila., Chairman,
J. D. IMBODEN, Richmond, Va.,
CHARLES STAPLES, Portland, Me.,
G. L. REDD, Clearfield, Pa.,
DAV. McHARDY, Aberdeen, Scotland,
T. DIEFFENBACH, Germany.

Group
Judges
XV.

We annex a sample of the testimonials we receive daily from all parts of the country:

ST. LOUIS, Mo., June 8, 1877.
GLOBE NAIL CO., BOSTON, MASS.

Gentlemen: Find enclosed advertisement and postal card concerning your Nail. (Referring to a scurrilous advertisement and postal card, disparaging the Globe Nail, circulated by a rival manufacturer over the humbug signature of "Humane Society for the Prevention of Cruelty to Animals." No Society bearing that title ever existed.) As I take a great interest in the prevention of cruelty to animals, —horses in particular,—I desire to say a few words in favor of The Globe Nail. Though I am not a very extensive Horse Shoer, yet I have used enough Nails of the different makes to speak knowingly. I have used the Globe Nail in my shop and on the race track for six years, on all classes of horses, from the heavy draft horse to the tender footed running horse; and I can safely say it has no superior in point of Toughness, Shape, and Finish, if it has any equal. I have used about fifteen hundred pounds of Globe Nails a year for the last six years, and in that time I have found four imperfect Nails, two of which I returned to you about two years ago and received in return four perfect ones, for which accept my thanks. If my men had no better sense than to drive those imperfect Nails in a horse's foot, I would not consider it the fault of the Nail if the horse was lamed. If bosses would look more to the competency of their men and less to trying to get shoeing nails a few cents a pound cheaper, we would have fewer lame horses. I know for safety and durability, with a man who understands his business to drive them, your Nails can't be beat! I am willing to pay, without any suit, for all horses that are lamed in my shop by using the Globe Nail. As long as it is made as at present, I shall continue to use it, even if I could get other Nails for nothing. I consider it the safest Nail that was ever driven in a horse's foot.

Yours Very Respectfully,

(Signed.)

P. H. O'NEILL,

Horse Shoer, No. 1007 Broadway.

P. S.—I think I could get every boss in St. Louis to sign this if I thought it necessary.

P. H. O'N.

The best Horse is sure to win. SO
CLEAR THE TRACK FOR THE

Descriptive Catalogues free to all applicants.

A COPPER BULL-RING,

2½ inches in diameter, of the most approved pattern, with screw-driver for putting it together, will be sent, prepaid, on receipt of \$1.00. Address

ORANGE JUDD CO., 245 Broadway, New York.

NEW CHAMPION MOWER.

This peculiar Machine is unlike any other ever made, and is a new departure in the construction and mode of operating Mowing Machines.

IT NEVER RECEIVED A FAINT-HEARTED ENDORSEMENT.

- "Light of draft, and under perfect control."
- "The knife will run at any angle."
- "Can be speedily adjusted while in operation."
- "It can be instantly thrown out of gear."
- "Can be put in working order in a minute."
- "The bar can be lifted upright to pass a tree."
- "Movement of the knife, uniform and powerful."
- "The wheels are wide apart to stride the swath."
- "Two cog-wheels, the size of a dinner-plate."
- "No pitman, and no gearing in the drive wheel."
- "The gearing enclosed in one small disk."
- "The old style of quick running-gearing discarded."
- "Is particularly adapted to uneven ground."
- "It cuts where all other mowers fail."
- "Will cut among stumps and over gutters."
- "It does not clog in swampy marsh or bog."
- "It will work through gullies and over ridges."
- "It will mow the shortest and down grass."
- "It cuts through thick and thin."
- "It is equal to any emergency."
- "It is nearly noiseless in action."
- "No lost motion, and no perceptible wear."
- "It excels all machines in use at present."
- "No side draft, no bearing down on horses necks."
- "The most complete and perfect machine."
- "I would not exchange it for any other."
- "It will last a life time."
- "Sixty-two cents for repairs in four years."

From every Fair and Agricultural Exhibition at which it was presented last season, the New Champion bore away, with only two exceptions, the First Honors—The Red Ribbons.

Do not purchase a Mower until you have examined the NEW CHAMPION. "When you have tried it, you will buy no other."

For full particulars address: Whiteley, Fassler & Kelley, The Champion Machine Company, and Warder, Mitchell & Co., Springfield, O.; and The Toronto Reaper and Mower Company, Toronto, Canada.

FARM TALK:

A Series of Articles in the Colloquial Style, illustrating Various Common

Farm Topics.

By GEO. E. BRACKETT.

CONTENTS:—Guess Farming; Pedigree Corn; About Hay-making; Fancy Farmers; When to sell Produce; Butter Making; Getting Ready for the Cattle Show; Agricultural Colleges; Apple Trees and Insects; Middle Men; Taking the Papers; The 'Ologies; An Evening's Chat; Planting for Posterity; Road Making and Breaking; In the Barn; How Trees Grow; Pigs and Poultry; Farm Fences; Out in the Fields.

Price, post-paid, paper covers, 50 cts.; cloth, 75 cts.

Plain Directions for the Construction and Erection of Lightning Rods.

A work, written not in the interest of any patent or special manufacture, but solely for the purpose of teaching any ordinarily skillful mechanic how to put up a rod that will really ensure safety, and of enabling every householder to decide whether or not his house is perfectly protected. By JOHN PHIN, C. E.

Price, post-paid, 50 cts.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD COMPANY,
245 BROADWAY, NEW YORK.

Stockbridge Manures

Originated by Prof. STOCKBRIDGE,
Professor of Agriculture in the
MASS. AGRICULTURAL COLLEGE.

A special manure is made for each Farm and Garden Crop, containing the Plant-Food which each particular Plant requires. These manures were used on more than 10,000 acres in 1877, and with Great Success.

HUNGARIAN OR MILLET.

For 1 acre 2 Bags, 320 lbs., \$10, or 450 lbs., \$14.

This crop is a strong feeder. Two to three tons per acre is not an unusual yield, and, cut early, it is considered equal to the best English hay. It thrives best in hot, dry weather, and may be sown from the middle of June to the first of August, and grows in six weeks, and may be taken off in time to seed down in the fall, or sow to winter Rye or Wheat. Hungarian is a grand thing, and is not half appreciated by our farmers. About one bushel seed is sown to the acre. It should be cut when in blossom.

BOWKER'S WHEAT MANURE Per ton, \$40; per hundred, \$2.25.
BOWKER'S BUCKWHEAT MANURE

The manures used in any quantity will yield excellent returns, as they are prepared with especial reference to the needs of the crops, and should be used according to the condition of the land sown, from 200 to 600 lbs. per acre.

Send for Pamphlet for 1878, mailed free.

Allen's American Cattle.....\$2.50

Their History, Breeding, and Management. This book will be considered indispensable by every breeder of live-stock. The large experience of the author in improving the character of American herds adds to the weight of his observations, and has enabled him to produce a work which will at once make good its claims as a standard authority on the subject. An excellent feature of the volume is its orderly, methodical arrangement, condensing a great variety of information into a comparatively small compass, and enabling the reader to find the point on which he is seeking light, without wasting his time in turning over the leaves. By LEWIS F. ALLEN. Illustrated. Cloth, 12mo.

Allen's New American Farm Book...\$2.50

Allen's American Farm Book, (the former edition of the present volume), has been one of the standard farmers' hand-books for twenty years; it is still a valuable book, but as its author, Mr. R. L. Allen, could not give time to its revision, this was undertaken by his brother, Hon. Lewis F. Allen, the distinguished farmer of Erie county, editor of the American Shorthorn Herd-Book. The present edition of the work is greatly enlarged, and full of suggestions from the rich experience of its editor and reviser, and is called the NEW AMERICAN FARM BOOK. Originally by RICHARD L. ALLEN, Revised and greatly enlarged by LEWIS F. ALLEN. Cloth, 12mo.

Swine Husbandry.....\$1.75

A most valuable Practical Manual for the Breeding, Rearing, and Management of Swine, and the Prevention and Treatment of their Diseases. While written from a Western breeder's standpoint, the usefulness of the book is by no means limited to any section of the country. It is the fullest and freshest compendium relating to Swine Breeding yet offered. By F. D. COBURN, a Western Practical Farmer and Breeder.—N. B.—If this \$1.75 book be selected for the extraordinary premium for two subscribers, 15 cts extra must be remitted. Cloth, 12mo.

Harris on the Pig.....\$1.50

The points of the various English and American breeds are thoroughly discussed, and the great advantage of using thorough-bred males clearly shown. The work is equally valuable to the farmer who keeps but few pigs, and to the breeder on an extensive scale. By JOSEPH HARRIS, author of "Walks and Talks on the Farm," etc. With numerous Illustrations. Cloth, 12mo.

Dadd's American Cattle Doctor....\$1.50

To Help Every Man to be his own Cattle-Doctor. A work by GEO. H. DADD, M.D., Veterinary Practitioner; giving the necessary information for preserving the Health and Curing the Diseases of Oxen, Cows, Sheep, and Swine, with a great variety of original Recipes, and valuable information on Farm and Dairy Management. Cloth, 12mo.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD COMPANY,
245 BROADWAY, NEW YORK.

AUGUST, 1878.

AMERICAN AGRICULTURIST

FOR THE FARM, GARDEN & HOUSEHOLD.

VOL. XXXVII.

NUMBER 8.

PUBLISHED BY THE
ORANGE JUDD COMPANY
245 BROADWAY,
NEW-YORK.

ASHTON'S FACTORY FILLED SALT.

**THE BEST FOR BUTTER AND CHEESE.
THE BEST FOR STOCK.
THE BEST FOR HOUSEHOLD PURPOSES.
THE BEST FOR PROVISIONS.**

In order to bring Ashton's Salt within the reach of **Farm Dairies and Household Consumers**, it is now imported in **56 lb. Bags**, as well as in **224 lb. Sacks**, and should **AT ONCE** be in use

IN EVERY FAMILY, ON EVERY FARM.

A sack of Ashton's Factory Filled Salt contains over half a bushel more than a sack of Higgin's Eureka Salt, and about a bushel more than a 380 lb. barrel of Onondaga Salt. It takes from three to six pounds of Ashton's Salt to one hundred pounds of butter, and not to exceed three pounds to one hundred pounds of cheese, so that the extra cost of using Ashton's, which enhances the value of butter from two to five cents per pound, and cheese from one-half to one cent per pound, is not worthy of consideration; the butter is increased in value \$2 to \$5 per hundred pounds, at an extra cost of not to exceed 1½ cent to 3 cents for salt; the cheese is increased in value 50 cents to \$1 per hundred pounds, at a cost not exceeding 1½ cent for salt over the lowest priced salt used in the Dairy. In fact, there is no investment that pays the butter and cheese maker so well as the purchase of Ashton's Salt.

FRANCIS D. MOULTON & CO.,

Sole Agents for the United States and Canada, 105 Water St., New York.

DOWNING'S LANDSCAPE GARDENING.

A TREATISE ON THE

Theory and Practice of Landscape Gardening

ADAPTED TO

NORTH AMERICA;

WITH A VIEW TO THE

Improvement of Country Residences.

Comprising historical notices and general principles of the art, directions for laying out grounds and arranging plantations, the description and cultivation of hardy trees, decorative accompaniments of the house and grounds, the formation of pieces of artificial water, flower gardens, etc.,—with

Remarks on Rural Architecture.

By the late **A. J. DOWNING, Esq.**

WITH A SUPPLEMENT,

containing some remarks about country places, and the best methods of making them; also an account of the newer decorations and evergreen plants, lately introduced into cultivation, both hardy and half-hardy.

AND A SECOND SUPPLEMENT,

bringing down to the present time some brief account of the various trees and shrubs which have been introduced since the former Supplement was published, (in 1839).

By **HENRY WINTHROP SARGENT.**

BEAUTIFULLY ILLUSTRATED,

with thirty-nine engravings on wood, six on stone, and six on steel, one of which is a fine portrait of the author.

Price, Post-Paid, - - - **\$6.50**

LANDSCAPE ARCHITECTURE,

as applied to the

WANTS OF THE WEST.

With an Essay on

Forest Planting on the Great Plains.

By **H. W. S. CLEVELAND,**
Landscape Architect.

The object of the author is to show that, by whatever name it may be called, the sub-division and arrangement of land for the occupation of civilized men, is an art demanding the exercise of ingenuity, judgment and taste, and one which nearly concerns the interests of real estate proprietors, and the welfare and happiness of all future occupants.

Price, post-paid, - - - **\$1.50**

DWYER'S HORSE BOOK. SEATS AND SADDLES, BITS AND BITTING.

**THE PREVENTION AND CURE OF
RESTIVENESS IN HORSES.**

By **FRANCIS DWYER.**

Major of Hussars in the Imperial Austrian Service.

PRICE, POST-PAID, \$2.00.

DISEASES OF THE HORSE, AND HOW TO TREAT THEM.

By **ROBERT CHAWNER, Veterinary Surgeon.**

A concise Manual of Special Pathology, for the use of Horsemen, Farmers, Stock-Raisers, and Students in Agricultural Colleges in the United States.

PRICE, POST-PAID, \$1.25.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD COMPANY,
245 BROADWAY, NEW YORK.

THE MARKET ASSISTANT,

Containing a brief description of every Article of Human Food Sold in the Public Markets of the cities of New York, Boston, Philadelphia, and Brooklyn; including the various Domestic and Wild

Animals, Poultry, Game, Fish, Vegetables, Fruits, etc., with many Curious Incidents and Anecdotes, by

THOMAS F. DE VOE,

Author of "The Market Book," etc.

ILLUSTRATED.

The object of this volume is to present that which may be found practically useful as well as interesting. It aims at bringing together, in as small compass as possible, and in a form easy of reference, those items of information which many would desire to possess when called upon to cater for the household.

SENT POST-PAID, - - - PRICE \$2.50.

NEW AMERICAN FARM BOOK.

Originally by **RICHARD L. ALLEN.**

Revised and greatly enlarged

By **LEWIS F. ALLEN.**

PRICE, POST-PAID, \$2.50.

Allen's American Farm Book has been one of the standard farmers' hand-books for twenty years; it is still a valuable book, but not up to the times; and as its author, Mr. R. L. Allen, could not give time to its revision, this was undertaken by his brother, Hon. Lewis F. Allen, the distinguished farmer of Erie county, editor of the American Shorthorn Herd-Book. The work is greatly enlarged, and full of suggestions from the rich experience of its editor and reviser, and is called the *New American Farm Book*.

AMERICAN CATTLE.

Their History, Breeding, and Management.

By **LEWIS F. ALLEN.**

ILLUSTRATED. PRICE, POST-PAID, \$2.50.

This book will be considered indispensable by every breeder of live-stock. The large experience of the author in improving the character of American herds adds to the weight of his observations, and has enabled him to produce a work which will at once make good its claim as a standard authority on the subject. An excellent feature of the volume is its orderly, methodical arrangement, condensing a great variety of information into a comparatively small compass, and enabling the reader to find the point on which he is seeking light, without wasting his time in turning over the leaves.

PARSONS ON THE ROSE.

A Treatise on the Propagation, Culture, and History of the Rose.

REVISED AND NEWLY ELECTROTYPED.

By **SAMUEL B. PARSONS.**

ILLUSTRATED. PRICE, POST-PAID, \$1.50.

The Rose is the only flower that can be said to have a history. It is popular now and was so centuries ago. In his work upon the Rose, Mr. Parsons has gathered up the curious legends concerning the flower, and gives us an idea of the esteem in which it was held in former times. A simple garden classification has been adopted, and the leading varieties under each class enumerated and briefly described. The chapters on multiplication, cultivation, and training, are very full, and the work is altogether the most complete of any before the public.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD COMPANY,
245 BROADWAY, NEW YORK.

Test Your Soils for Wheat & Grass. Complete Manure Set.

Consists of four uniform weight (50 lbs.) bags—to be applied on four uniform sized plots. Requires no preparation or mixing—is ready for use—and may be applied by any ordinary farm hand.

Price—including cartage—Per Set, \$5.00.

Address **THE MAPES FORMULA AND PERUVIAN GUANO CO.,**

158 Front Street, New York.

For further description, see page 311.

WALTHAM WATCHES.

We beg to announce that we have recently entirely remodeled the very popular grades of full-plate movements, known by the marks, "Wm. Ellery," "Appleton, Tracy & Co.," "Waltham Watch Co.," "P. S. Bartlett," and "Broadway," giving to them not only a highly improved appearance, but great additional value. We embody in them such of the best results of our experience and study for twenty years as can be useful in this popular form of watch. We give these new model watches special recommendation to all who look for good performance and solid excellence at moderate cost. The alterations have been made with the view of pleasing practical watch makers, as well as watch wearers.

No watches retailed by the Company. Apply to your local jeweler.

Terms, Publishers' Notices, etc.

Subscription Rates of the American Agriculturist,
postage prepaid by the Publishers: One Copy, \$1.60 a year;
Two Copies, \$3; Three Copies, \$4.20 (\$1.40 each); Four Copies,
\$5.20 (\$1.30 each); Five to Nine Copies, \$1.25 each; Ten to
Nineteen Copies, \$1.20 each; Twenty Copies and upwards,
\$1.10 each; Single Numbers, 15 cents, post-paid.—The above
terms are for the United States and Territories, and British
America. To the above add 14 cents extra per year for
papers delivered by mail in N. Y. City, and for copies sent
outside of the United States and British America, ex-
cept to Africa, Brazil, British Honduras, the East Indies,
and Mexico. For the last named five countries the extra
charge is 38 cents per year, to cover extra postage; Single
Numbers, 17 cents, post-paid. Remittances, payable to
Order of Orange Judd Company, may be sent in form of
Checks or Drafts on N. Y. City Banks or Bankers; or P. O.
Money Orders; or in Registered Letters, such letters to
have the money enclosed in the presence of the Postmaster,
and his receipt taken for it, and the postage and registering
to be put on in stamps. Money remitted in any one of the
above three methods is safe against loss. Bound Volumes
from Vol. 16 to 36 inclusive, supplied at \$2 each, or \$3.30 if to
be sent by mail. Sets of numbers sent to the office will be
bound in our regular style for 75 cents (30 cents extra if to
be returned by mail). Missing numbers for such volumes
supplied at 12 cents each.—Any Numbers of the paper is-
sued for 21 years past, sent post paid for 15 cents each;
or any full year, sent unbound, for \$1.60. Clubs of
Subscribers can be increased at any time, at the club rates,
if new members begin at same date as original club.

**Every German Cultivator and Laborer
on the Farm, or in the Garden, OUGHT**
to have the German *American Agriculturist*, and thou-
sands of new subscribers are taking it this year. It

contains not only the Engravings and all the essential
reading matter of the American edition, but an additional
Special German Department, edited by the Hon. Frederick
Münch, of Missouri, a skillful and successful cultivator
and excellent writer. No other German Agricultural or
Horticultural Journal in America has been so long issued;
no other contains so much useful information and so many
engravings. Germans are a reading, thinking people,
and know how to make good use of what they read.
Many Americans supply it to their German laborers and
gardeners; all would find it pay to do so. — *Nothing*
else can compete with it in cheapness of price for the same
amount of material, engravings, etc., because the expense
of collecting and making these is largely borne by the
American edition, and no separate office or machinery is
required beyond German editors and the printers. Its
terms are the same as the American edition, singly and
in clubs; and clubs can be composed of subscribers for
either edition in whole, or in part. — *Please call the*
attention of your German neighbors to this paper. It will
*do much to help new comers to a knowledge of the sys-
tem and modes of culture used in this country.*

**Potato-Diggers, Flouring Mills, and all other
implements, will be found mentioned in our ad-
vertising columns, which may always be looked to as a
"Directory" for farm supplies, often at a great saving in
time and postage on the part of correspondents.**

Preserving Powders.—There are other chemical
compounds besides the *Chloride of Sodium*, or common
salt, which have the power of arresting decay in animal
and vegetable substances. For several years these have
been offered to the public for the preservation of fruits,
etc. When an advertisement of this kind is presented to
us, the first condition is, that we shall be informed of the
precise composition of the article. If we regard the com-
pound as a safe one, the advertisement is admitted. To
avoid answering special inquiries, we would say that so
far as regards the articles offered in former years, and
those advertised the present year, we have every reason
to believe that they may be employed for preserving pur-
poses, without impairing the safety as food of the articles
preserved by this agency.

A Blunder was made in the description of the
"Farmer's Friend Grain Drill" in the July number,
wherein it was stated that 'by a simple arrangement the
implement could be transformed into a wheat hoe. Al-
though we had not seen the attachment, we had under-
stood this to be one of its desirable features. Well, it
was our blunder, and so much the worse for the "Far-
mer's Friend;" but the manufacturers are honest, and
"do not want to make any misrepresentations."

Trouble with Specimens by Mail.—We
have heretofore called attention to the trouble we have
with plants, etc., sent us by mail. After exercising all
care, we still have several letters referring to specimens
which have not reached us, and a number of specimens
of plants, insects, etc., to which we have no clue. When
one has taken the pains to send a specimen by mail, it is
a fair indication that he really wishes to know something
about it, and we have every desire to gratify his wish;
but if three or four specimens of grasses, for example, as
sometimes happens, come in one day, and there is neither
postmark, nor sign, to tell to whom they belong, we are
quite unable to make them useful. By far the safest way
is to send specimens of moderate size in a letter; it
rarely occurs that the grass or other plant is large
enough to more than double the ordinary letter-postage,
and we are sure of its safe arrival (which, in the other
case, we are not), and of knowing from whom it comes.
... Some one in Minn., having a new raspberry, wishes
our opinion of it. It is just possible, that by great care a
perishable fruit like this might be sent so far by mail,
and arrive in fair order, but highly improbable. Our cor-
respondent wraps some berries in cotton, puts them in a
frail paper box, ties it with a string, and sends it. We
receive a crushed box, containing some matted cotton,

in which are imbedded some raspberry seeds. Not the slightest trace of a berry, except these seeds, and the jam. Had not the cotton fortunately absorbed the juice, the parcel would have been thrown out as injurious to other mail matter. It is not safe to send fruit, insects, or anything that can be crushed, in any other than wooden or tin boxes. We ask our friends, for their own sake, to endeavor that these specimens shall not only reach us in good order, but that they may be so marked that we can identify the owner. As it is, about half of those sent fail of their object through no fault of ours.

"The Sportsman's Library of Standard Works," is the title of a beautifully illustrated Catalogue, just issued by the Orange Judd Company. Some account is given of the various works on Hunting, Fishing, Shooting, Horses, Dogs, and also the popular works on Natural History of most interest to the sportsman. The engravings are abundant, and add much to the interest of the Catalogue, which is sent to any address for two 3-cent postage-stamps.

Cranberries.—"S. G. R.," Hion, N. Y. The requisites are a peat bog, an abundance of pure sand, and water under such control that it may be let off or on to the plantation as may be needed. "Cranberry Culture," by J. J. White, published by the Orange Judd Co. (\$1.25), gives every needed particular, and is by far the best guide that we know of.

Disease in Sheep.—"P.," Brunswick, Ga. A soft, loose swelling under the jaw in sheep is indicative of a dropsical effusion, caused by disease of the lungs or liver. It accompanies pleurisy and pneumonia, and is known as "liver rot." Alone, it is not sufficient to indicate fully the condition of the sheep, and no treatment can be suggested without further information. For full directions for determining the nature of the disease, and proper treatment, consult *Stewart's Shepherd's Manual*.

American Berkshire Record.—Pedigree goes for something either good or bad; and a record that shows a valued ancestry is a considerable item in the salable estimate of either a horse, a bull, a cow, or a pig. This fact has tended to the successful establishment of the Berkshire Swine Record, of which the third volume is now in course of preparation. Entries for this volume can be sent to P. M. Springer, Springfield, Ill., Secretary of the American Berkshire Association.

"Food from the Far West."—We do not know just where the "Far West" is, but an intelligent Scotchman, James Macdonald, has found it in Texas, Nebraska, Kansas, Iowa, and the neighboring States, and gives in a work with the above title the results of his observations during a protracted tour in our cattle-raising States. It is sometimes an advantage to have portions of our own country described by a stranger, as many points which an American regards as matters of course, strike him as novel and of interest, and if the writer from abroad be a good observer, he is likely to give us a fuller account than would an American describing the same territory. In the present book we find the whole subject of cattle, sheep, and hog raising in the Western States discussed in detail, and by a disinterested observer. It is a work that can not fail to be of value to those who contemplate entering into this branch of agriculture, and to those who are engaged in the exportation of meat to other countries. Those who are interested in the development of this branch of industry, as related to our national prosperity, will find here a vast fund of information upon food supply—a subject of interest both at home and abroad. Published in London, Eng. For sale by the Orange Judd Co.; price, \$1.50.

"House Drainage and Water Service in Cities, Villages, and Rural Neighborhoods," by James C. Bayles, New York: David Williams. This is a large octavo of 360 pages, with numerous wood-cuts and working drawings. A work of this importance requires more careful study than this mid-summer weather will allow, and we can only at present say that we are most favorably impressed with its apparent thoroughness and completeness. It, while giving full plans for supplying water to and carrying off the wastes of costly city-houses, does not omit the wants of the humblest farm-house, but it gives the simple earth-closet—without machinery, which we have on several occasions presented to the readers of the *American Agriculturist*. A copious index and marginal references add greatly to the value of the work. Sent from this office, post-paid, for the publisher's price, \$3.

Grafting and Budding.—Several years ago, we had occasion to notice "*L'Art de Greffer*," by Chas. Ballet, who kindly, through a mutual friend, sent us a copy of the work in the original French. Since then it has been translated into English, and published by Macmillan & Co., London, Eng. It is the most complete work on grafting—including budding—in any language,

and though the American propagator may not need to use many of the processes here described, it is well for him to know about them. We know of no other work that is so full on this method of propagation in all its varieties. It can be sent from this office post-paid for its price, \$1.75.

"How We Raised the Baby," is the title of a handsomely gotten up work by Derby Brothers, New York, written by "A Benedict," with a preface by the author of "Helen's Babies." It is well written in a pleasing style, and, so far as we have examined it, is a work which young mothers will welcome, giving both instruction and pleasure. Price, paper, 50c.; cloth, \$1.00.

Book for Shepherds.—"A. J. K." Springfield, Ill. Randall's Practical Shepherd is a very good book, but is not modern. Randall's Sheep Husbandry relates chiefly to the Southern States. A modern book, which includes all that is valuable in other works, and contains much new matter that is found in no other, is Stewart's Shepherd's Manual. This describes all the newer breeds, and even the cross-bred sheep, that are now coming into notoriety.

Poultry Journal.—"R. G.," Allegheny Co., Pa. The *American Agriculturist* contains every month much information regarding the breeds and management of poultry. Those, however, who desire a journal entirely devoted to poultry, will find an excellent one in the "Poultry World," Hartford, Conn.

A New Work on Birds, by the rising naturalist, C. J. Maynard, of Newtonville, Mass., is now being issued by the author. It is called "The Birds of Florida, with the Water and Game Birds of Eastern North America," and, with its appendix, is intended to describe all the birds occurring between the Mississippi and Atlantic Ocean. We say a "new work," though it is a new and revised edition, with many additions and improvements, of a work previously issued. With its additions it is practically new. Though it might have been somewhat condensed, it is a work full of interest to the lover and student of birds. The 16 plates, hand colored, are of new or little known species, and are handsome and life-like. The work has the charm of originality, being mostly from the author's own notes, gathered during 15 years of study and observation. It is issued in monthly parts, 16 in all; five are now out. Price, 85 cts. a number.

Harrison's New Standard Flouring Mill has, we understand, been recently improved by doubling the discharge spout, by the addition of a safety spring, which prevents damage from the passage of stones, nails, etc., and the substitution of a steel spindle in place of an iron one. Thus fitted out, these mills are doubtless equal to many years of grinding, as they are honestly made in other respects.

Clawson Wheat.—Our contributor, Joseph Harris, who talks about Crops on Moreton Farm, sends us specimens of heads from his crop of Clawson wheat. Being several years ago convinced of the value of this variety as a white winter wheat, he has taken pains to keep it pure and to introduce it to the attention of other wheat growers. The specimens, in both head and grain, warrant Mr. H's. high opinion of it. He offers it to those who wish to test it on very moderate terms.

Wheat on Poor Land.—"J. H. T.," Portage Co., Ohio. For a very poor soil, either of the special wheat manures made by Bowker & Co., or the Mapes Formula Co., could be used with the probability of success. It should be sown on harrowed ground, and harrowed in, after which the seed is to be sown. A very popular wheat is the Clawson. Fall wheat should be sown about the middle of September, or later where the fly is feared. Clover may be sown until early in the spring, or about the first of August, which some prefer as the best time.

Experiments with Wheat.—Last spring the *American Agriculturist* inaugurated some important farm experiments with fertilizers, which created a great interest, and are being carried out by a large number of farmers in various sections of the country, and with quite satisfactory results thus far. We are pleased to learn that this good work is to be continued by at least one prominent fertilizer house. The Mapes Fertilizer Company have arranged a "Complete Manure" set, on a simple and easily understood plan, which they offer to send to farmers at a merely nominal cost, as compared with the work and expense involved, especially for trial this fall on wheat, rye, and grass. There are four bags in the set, of a uniform size of 50 lbs. each, to be used on uniform sized plots. No. 1 is a complete fertilizer, containing nitrogen, phosphoric acid, and potash; Nos. 2, 3, and 4, are the same as No. 1, save that the nitrogen is left out in one, phosphoric acid in another, and potash in the last, thus covering the ground in a simple manner. These

experiments, while they may not tell just what and how much any particular soil lacks, and must be continued perhaps for years in order to reach any definite results, are instructive and valuable for any farmer to try, as they familiarize him with the substances employed, and teach many principles in the use of artificial fertilizers, which are fast becoming a necessity in American agriculture.

Reliable Business Men, those who have both the ability and the intention to do what they promise, are the only ones invited to use the business-pages of this journal, and those in charge of that department are under positive instructions to admit no others at any price, and they try to live up to it, and generally do, though once in a while they may make a mistake—to err is human—but this seldom occurs. We could make a fortune in a single year, and supply the paper at lower rates, if the advertising pages were thrown open to those who gladly pay high prices, as they can afford to, because they give little for much. But we mean our advertising pages shall be a valuable source of trustworthy information to our readers.—When ordering from, or corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of this Journal. They will know what we expect, and what you expect of them as to prompt and fair treatment.

Ashton's Factory-Filled Salt.—There are certain products which have a world-wide reputation; this has been established by observing through a long series of years a uniformly high standard of excellence. Among the various brands of Salt in the market, none has, to say the least, a better reputation among dairymen than the Ashton, and this has been acquired by preserving a high quality as to purity—and, what is of equal importance, a uniform texture as to grain. But our present object is not to extol the quality of the Ashton salt—a task as useless as to praise Day & Martin's Blacking, or Crosse & Blackwell's Worcestershire Sauce—articles to be found in every port in the world. The reputation of this salt was made many years ago, and its excellence has been frequently alluded to in these columns. The object of the present notice is to call the attention of those who have found the sacks of 250 lbs., in which this salt could heretofore only be obtained, inconveniently large, to the fact that it is now put up in small bags of 56 lbs. each, and the small dairyman can now purchase the salt in quantities suited to his needs, and of a quality guaranteed to be equal to that in the larger sacks.

An Interesting Excursion.—Our readers can not spend their leisure more pleasantly than in visiting regions whose magnificent imposing scenery enlarges one's ideas, lifts him, so to speak, out of himself, and carries him nearer to the Creator, through a contemplation of His wonderful works. Excursions are now arranged by the various public thoroughfares at so reasonable rates, that the farmers, after the labors of the harvest are ended, and at other periods, when work does not press, can take their families on jaunts of a few days for a comparatively small outlay. There is no locality in the Middle States which presents more magnificent natural scenery, more objects of interest and instruction, than what is known as the Lehigh mining region of Pennsylvania; extending from Bethlehem through the Lehigh Valley to Wilkesbarre. Two of our associates have this week returned from a visit thither. One of them, after travelling eight thousand miles through the Rocky Mountains and the far Western States and Territories, says that he nowhere found more imposing and romantic scenery, than he has now met with during his last week's jaunt in the Lehigh Valley. There are numerous railroad routes which convey visitors to this region, whether coming from the East or West. Two entire days should be spent at Mauch Chunk, where the Coal Mines, the "Switch Back" Railroad, Mt. Pisgah, Mt. Jefferson, Panther Creek Gorge, Onoko Glen, with its innumerable cascades and waterfalls, and many other points of attraction, afford a succession of gratifying surprises for the tourist.

The Interesting Market Tables, 1 to 5, on page 285, are, as usual, instructive—especially Table 3. The exports of Wheat since Jan. 1, have been nearly six times greater than last year, or 23,216,000 bushels against 4,640,064. Taking the flour as wheat, (5 bushels to the barrel), the excess this year is 23,443,881 bushels, or an excess of two million bushels over the greatest entire export for any season during six years previous. Many other figures in the several tables will repay careful study and comparison.

Herdin Sheep.—"K.," Half Day, Ill. One man can herd 2,000 sheep upon the plains with the help of a boy and two dogs. To herd 1,000 will require as much help. There is no better grain than corn for yield, ease of growing, and for use in feeding sheep. One ear per sheep each day, or one pint of shelled grain, is sufficient, with fair pasturage.

AMERICAN AGRICULTURIST

New York, August, 1878.

Agriculture of the Nile.

The plow-team in the picture tells the story of Nile farming in a simple, straightforward manner. In the strangely inharmonious outlines of the camel and the ox, one can trace the geography of the country thereabout: The desert has come to the Nile for drink, and to its harvest fields for food. The desert is but close at hand, just back of the bordering lands which feel the hand of the Nile-god in the moisture of the air, and receive his mantle of over-flowing waters. The incongruity of the mating indicates the half-civilized condition of the people, the mass of whom are living as their fathers lived centuries ago, who harness the camel and ox, use the same plow, plow just as deep, sow the same seed, cultivate the same crops in the same manner, are guided by the rise and fall of the Nile waters, and look upon the Nile-god as a deity rul-

light and easy to work that only the simplest and least costly of implements are required. They can live in ease, and revere and follow the customs of their fathers; for the Nile-god is the same yesterday, to-day, and—to-morrow will take care of itself. Such is the story of the plow. No need, then, you see, of an "Adamant," a "Patent Chilled Oliver," a "Centennial," or a "Holbrook." It does its work. "Let well enough alone," is the motto of that people. The turbaned plowman corroborates the tale of the team and of the plow. But he tells more: his clothing speaks of another race of fierce, hardy people, who, ages ago, came from the East and overran this land, bringing destruction to everything save the pyramids, the sphinx, the Nile, and the desert.

Hints for Work.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

An Explanation.—When we consider the vast territory over which the *American Agriculturist* circulates, and the great difference in the seasons, it is obvious that these hints cannot be used by all read-

is filled with weeds—of which the sprouting oats are the worst—and the rag-weed, and many others work mischief. An important needed improvement in agriculture is

A Change of Rotation.—With the present rapidly changing demands upon farmers for a greater variety of food products, we need a changed system of agriculture. The production of meat will have to be the chief aim of a large number. There is a widening demand for milk and cheese, and for the best grades of mutton sheep. All these are products of the highest systems of farming, in which the soil must be enriched and kept clear of weeds, so as to produce maximum crops of fodder that can be manufactured on the farm into these most salable articles. The old plan of rotation—grass and clover, corn, oats, and wheat—in which the three grain crops following each other, are not well adapted to cattle feeding, especially the last two—must be abandoned if we are to derive any advantage from the new demands and markets so auspiciously opening for us in Europe.

Drilling Wheat.—It would be an interesting and we believe a profitable experiment to sow at least one acre of wheat in drills, so far apart, that the crop could be cultivated. This may be done by tying each two of the drill spouts together, and thus discharging the seed into one furrow; sowing

A SCENE ON THE NILE. — FROM A SKETCH BY HOPPIN.

ing all their affairs, just as their fathers, and fathers' fathers, for many generations, did before them. The plow of the sketch would do very poor service in the hard soils of New England; on the prairies of the West it might do better. But it is made for a different condition of the agricultural soil. You see its story printed in plain characters on its rude mould-board, and share, and sole, which run together as one? It is as plain as the written language of the American Indian. It reads thus:

"There is no rain in this country; the Nile is fed by waters from the lakes and mountain streams of the far interior. The Nile-god knows that without rain his people can only water their crops by the severest of hard labor in irrigation. So once every year he calls upon the lakes and streams to fill the banks full to overflowing, and spreads out his mantle of water over the fields. As the waters subside, several inches of fine silt, brought from fertile woodlands at the source of the river, is left on the surface. This accumulation has gone on for centuries, so that it now composes the whole soil, which is so fine, light, and soft, that only this crooked stick is needed as a plow to stir it."

Thus the Nile-god cares for his people: he waters their lands, fertilizes the earth, gives them a soil so

ers alike. They must necessarily be general in character, and when it is not expressly stated that the remarks apply to a certain section, discretion must be used as to the time and manner of acting upon the hints given. For example, in regard to sowing, planting, harvesting, and such other work, it is evident that no one rule can apply everywhere; but it is easy for each reader to adapt the suggestion to his own locality.

Preparation for Wheat.—Harvest being over, the soil for the next crop needs to be prepared at once. In the Southern States, where sowing may be delayed for two months yet, a "pea-fallow" is an excellent preparation. Land may be plowed and harrowed and two bushels per acre of cow-peas sown. The seed is best covered with a five-tooth cultivator. The growth made when the time for wheat seeding arrives, is to be turned under carefully, and the ground leveled by drawing an inverted harrow over the field, which also helps to cover the vines. If cotton seed is used as a fertilizer, sow it upon the vines, before plowing under. In the north,

A Clover-sod, may be treated to a dressing of well rotted manure, and plowed late this month. Perhaps there can be no better method for wheat than this.

Wheat after Oats, is a faulty practice. The soil

somewhat less seed. Then the rows will be 12, 14, or 16 inches apart; and the spaces may be cultivated by adapting an ordinary spreading cultivator, or using a wheat hoe, such as has been often described in the *American Agriculturist*. A yield of 60 to 80 bushels per acre, has been obtained in this manner.

Seed.—As much depends on the variety of wheat sown as upon the manner or cultivation. Upon similar soil, and with the same treatment, one variety may yield twice as much as another. Of several new varieties tried by the writer the present season, the Clawson has excelled.

Early Sowing is preferable, except where there is danger of the Hessian fly; in which case sowing may be deferred until late next month; but of the two evils—the fly or late sowing—it is questionable which is the worse. Many good farmers believe liberal fertilizing, and the consequent vigorous growth, to be the best remedy against the pest. This, however, is a matter in which local circumstances must be well considered.

Rye.—The remarks relating to wheat apply equally to rye. Where the straw is salable, this is often a more valuable crop than wheat.

Fodder.—For fall fodder, white turnips may be sown this month. An oat stubble plowed and

fertilized, may easily produce 600 or 800 bushels per acre, well worth 10 cents a bushel for cows, sheep, or pigs, and which will keep until January in good condition. 300 lbs. per acre of artificial turnip manure, or superphosphate, will aid greatly.

Southern Fodder Crops.—In the South, fodder crops may be consumed upon the ground, and the labor of harvesting saved. Turnips may be thus used for sheep, cattle, or pigs. For fall pasture, hay, rye, wheat, oats, barley, or millet, may be sown late this month; but as a drouth may render the ground too hard for plowing, this work should be done at the earliest convenience.

Plowing.—No time should be lost in plowing the land intended for fall crops. A double benefit will accrue in avoiding the risk of a drouth-hardened soil, and at no other time can weeds be so easily killed as now. One or two workings with a cultivator, or harrowing before weeds go to seed, will effect a good fall-fallowing and add fertility to the soil.

Green Fodder not required for feeding should be cut and cured for winter use before ripening. A well-worked crop of fodder-corn may very well be followed by fall grain or turnips. No piece of arable ground should be left idle.

Winter Oats are a valuable crop for the South, and as far north as Virginia, but a trial last season convinced the writer that this is not a crop for the North. Not one plant survived from a bushel of seed sown. In the South, the seed is sown next month, but the ground should be fitted as soon as possible. 2½ to 3 bushels of seed per acre is required. For winter pasture, and cutting for early spring fodder, this is very valuable.

Artificial Fertilizers.—Experience gained the past season goes to show that liberal manuring is the most economical. We can see in the past harvest where five dollars worth more fertilizer per acre would have given twice that value of grain. There can be no doubt that artificial manuring must become a part of our settled practice in the future, and making a few careful experiments will give valuable experience as to the use of these fertilizers.

Reclaiming Waste Lands.—No farmer can now afford to let any of his land lie idle, especially swamp lands, which, when reclaimed, may make the richest part of the farm. The present month is a good time for the work. Drains may be opened, and brush cut now will rarely sprout again. In doing this work, it is best to clear thoroughly as one goes. The portion begun should be grubbed, levelled, plowed, and, if desired, sown to grass before a second plot is touched. By finishing an acre or two, something effective is performed, and there will not be the discouragement and dissatisfaction felt as when a large piece is begun and left unfinished.

Cows.—Now that pastures are dry and bare, a provision of green fodder will be found acceptable. When green fodder is given, a regular ration of one ounce of salt daily should be supplied. A cow giving 10 to 12 quarts of milk per day, will consume 80 pounds of green fodder with 4 quarts of grain, every 24 hours. Where green fodder is provided, it may be well to keep the cows in a dark stable during the heat of the day. The past month the writer has found a considerable difference in the yield of milk in favor of this mid-day shade and rest.

Horses.—A run in a pasture field at night will be very acceptable to the working horses. In close stables the flies greatly disturb them, which they escape in the field. After a day's work, to sponge the coat with clean water, having a dash of carbolic soap in it, will be refreshing and healthful, and will prevent much of the annoyance from flies. Cleanliness will almost entirely avoid the disagreeable horse smell so prevalent in warm weather. The night's pasture should not be counted as part of the feed; the usual feed should be given before they are turned out in the evening.

Galls of the Skin.—Where the skin is chafed or galled by the harness, it should be washed with salt water, and, when dry, painted with spirits of turpentine. This will heal the raw spot, and keep off the flies. To prevent galls, scrape and wipe off with a wet cloth the harness where it presses closely upon the skin. Pads are to be avoided. A collar

or other part that will admit of a pad under it, fits badly, and is almost certain to produce galls.

Colts may now get a few oats daily as the grass fails. A shelter should be provided in the pasture where they can find shade; it should be in an airy part of the field, free from flies.

Sheep.—Ewes that are separated from the lambs should be closely watched, and the milk drawn from those whose udders are full. Where early lambs are wanted, the ewes should now be well fed; a pint of mixed rye, buckwheat and linseed meal may be given, and the ram introduced into the pen at night. For early lambs, the Southdown cross is preferable for quality, and the Cotswold for size. The flock will need the closest watchfulness just now; the gad-fly, dysentery, and the maggot are troublesome and dangerous enemies at this season. Count the flock every evening, and look up the stragglers without loss of time.

Pigs and Poultry, are omnivorous animals, and their tastes should be consulted. When in confinement, some fresh green food is needed, and a few chopped cabbages, or corn fodder will be greatly relished. Cleanliness in the pens will prevent disease, and keep vermin away. To keep places of this kind clean is much less trouble and labor than to make them clean when they have been neglected. Plenty of white wash inside will cleanse and sweeten.

How to Apply Whitewash.—Make a barrel full of lime-wash by slacking a bushel of fresh lime in a pork barrel, filling up the barrel with water, and stirring until thoroughly well mixed. Strain the wash into a pail as it is needed. With one of the Whitman Fountain Pumps give the walls and ceiling a douche bath of the lime wash, pumping it freely into the corners and crevices. With care, not a splash need come upon the clothes, and the hands may be protected by an old pair of mittens or a pair of old socks.

Notes for the Orchard and Garden.

Sufficient was said last month on the holiday of the orchardist and gardener, and on its profitable use. With many this will be the month of greatest leisure, and it will, we trust, be to many one of recreation; others having had their holiday, have already begun to look at the fall work. Of course, with such a wide circle, our Notes must always look forwards and backwards, and at the risk of much repetition we advise consulting "last month's Notes."

Orchard and Nursery.

We have before stated that, so far as the nursery is concerned, we do not pretend to act as a guide to the professional nurserymen, but only to give such hints as may be of use to those who propagate trees for their own or their neighbors' planting. We would especially call the attention of

Farmers' Boys to the fact that there is nothing in the whole routine of raising ordinary fruit-trees that is beyond their skill, and that there is a chance of adding essentially to their income, if they will supply such trees as their neighbors are likely to want. We can not, in these Notes, go into every

Nursery Detail, but the whole story is so plainly told by one of our most successful nurserymen, Mr. P. Barry, in his "Fruit Garden," that with this as a guide, we do not see how it is possible for any one of fair intelligence to go astray. It is worth while for young men, in localities where trees are likely to be in demand for some years to come, as they will be generally, to think of this matter.

There is no *Mystery* about any of the operations, of grafting and budding. Any boy who can make a willow whistle, can successfully perform these operations. It only needs a trial to show how easy both are. In a nursery the first need is

The Stocks, and these are for the most part raised from seed. Therefore, begin and collect peach-stones, etc. It is a notion among some peach-growers that only the seeds of the "native" or unbudded peach should be used for stocks. On the

other hand, excellent authorities claim that the seed of any *healthy peach* is as good as that of the "Indian" peach, and we really do not see why it should not be so. The peach-growers of Europe have no wild trees to supply them with stocks, and we hear no complaint on this account.

Apple and Pear Stocks are raised from miscellaneous seed, that of the pear being usually imported, while apple seeds are obtained from the pomace of the cider mills. When the operations are small, and most beginners will make their first attempts with hundreds instead of thousands, it is easy to get seed for stocks from the fruit eaten or otherwise disposed of in the family. Have boxes, pots, or other vessels of sand, put in convenient places, and let every member of the family who eats an apple or a pear, remove the seeds from the core, and cover them with the sand; let the same be done with fruit to be used for cooking. In this manner the beginner can procure all the apple and pear seeds he will need to plant for stocks next spring.

Gathering Fruit.—Sufficient was said last month on the summer varieties of apples. With early pears, special care is often needed, as most of these, if allowed to remain too long upon the tree, will decay at the core. Just so soon as a pear is mature, which may be known by the readiness with which the stem parts from the tree, even if still quite hard, the fruit should be picked and marketed, or if to be consumed at home, ripened in the house.

Marketing Pears, study the characteristics of each variety, and so arrange the picking that the fruit will be firm when it reaches the market.

Peaches should be the harder, the longer the distance they are to travel. Even for a near market, a single peach in the proper condition to eat, may become bruised, and spoil the appearance of the whole crate or basket. The peck basket, which we illustrated a few years ago, has now become common in city markets, but is still mainly used by dealers for repacking. Growers should study the wants of their market, and endeavor to supply them, and not leave these and the attendant profit to middle men. The success of growers of fruit of all kinds depends largely upon their

Commission Men.—Do not change consignees without due cause. Recollect that there is scarcely any business in which there are so many chances of going wrong as in handling fruit. The delay of a train for a few hours, while quite beyond the control of the consignee, may cause him to sell the fruit far below the rates of earlier arrivals. Fix upon your commission men early in the season, and stick to them until good reason is found for a change. Every fruit-producing district, the peach regions especially, is over-run with glib-tongued chaps, who are abundant with promises. Give little heed to such; as a general thing they are mere "sidewalk" dealers, with no "local habitation." It is a safe rule to consign fruit to well-established houses only. There are men who have been in the business for years, and who have worked hard to build up a reputation for fair dealing. Each city has such, and it will be well to find them out.

Young Trees will often suffer more severely this month than in any other, from dry weather, and even now, it may be necessary to apply a mulch—anything: straw, grass, chips, stones—whatever will cover the surface and prevent evaporation, to save them. On these young trees

Control the New Growth.—If shoots start where they are not wanted, rub them off. If some limbs are far ahead of others, check the rampant growers by pinching off their ends. The growth may be thus controlled, and future pruning avoided.

Insects are, as in other months, to be expected, and must be kept in control. The "Late," or "Fall-Web-Worm" will continue to weave its nets, and the shortest way is to cut off twigs and put them under-foot. Late broods of plant-lice may be destroyed by strong tobacco-water.

Budding is in season this month, according to the locality. In the Northern States, cherries, plums, and pears on their own stocks will be continued, or finished, while later in the month will be the usual time for budding peaches and pears on quince.

Fruit Garden.

The early crops being off, the plants must be treated with reference to next year's bearing.

Strawberries.—Growers differ as to the advisability of fall or spring planting. A new strawberry plant needs a full season's growth to become strong enough to bear a full crop. If the early runners remain where they take root, they will bear a crop next spring. If they are rooted in pots, and transferred to another bed, without any disturbance of the roots, they will bear well next year. This method, described more in full on p. 301, while very useful in private gardens, is not to be thought of by those who plant acres. If ordinary plants be set next spring, they will grow all the season, and give a crop the year following. If set this fall, they will make some growth, give a few berries next spring, but not a full crop until the next year.

Growers of Plants advise spring planting, and with good reason, their propagating beds keep pushing out runners, which take root and form new plants until cold weather checks them. If planting is done in the fall, it should be done early—not later than September; and to furnish plants at this time the nurseryman is obliged to waste many runners, which if left alone for a few weeks would make good plants for his spring sales.

In Fall Planting, the ground is in such excellent condition, and other work is not so pressing as in spring, that those who raise their own plants, will find it advantageous to set at this season. If the plants are at hand, they can be set early in September, after very hot weather is over; at this time the outer leaves of the plants should be removed, leaving only the central bud; if the season is favorable for a late growth, the chances are that a fair crop may be gathered next spring.

Blackberries and Raspberries.—The new growth to bear next year having been selected, all other shoots are to be destroyed. Pinching the growing end, when the canes are tall enough, as advised last month, will cause side shoots to grow, and these, when 12 or 18 inches long, according to the kind, are to have their growth stopped by pinching. Proper attention at this season will result in well-branched stocky plants, with abundant fruit next year. Black-caps and those red varieties that do not form suckers, are to have their new shoots required for next year's fruiting, similarly pinched, and all others, that will make the bush too dense, are to be removed.

Grape Vines need watching for the first appearance of mildew. Some varieties, especially those hybrids containing a cross of the European vine, are usually more susceptible to mildew than the natives. When the leaves of any vine in the collection, show grayish white spots on the underside, or the stems to the clusters show a mouldy appearance, apply sulphur to the whole, as it acts as a preventive, as well as a cure. The dealers furnish bellows for the purpose, which allow the under-side of the leaves to be reached. Apply on a still day, and diffuse a slight but uniform dusting over the whole vine. If laterals continue to push, pinch back as heretofore directed.

Dwarf Pears and such other large fruits as may be in the fruit garden, are to be treated as directed under "Orchard."

Insects, are still to be fought; the fall web-worm is not particular as to its choice, and spreads its net here and there. The large beetles and caterpillars upon the grape are to be hand-picked.

Kitchen and Market Garden.

This is a month of abundant returns from the garden, but it is also one of a rich harvest of weeds. The hot days are favorable to the destruction of weeds, and all work with the horse or hand implements tells most satisfactorily. Weed-killing—always in order—and the setting and sowing of a few late and succession crops are about all that will occupy the gardener, who will find in this of all working months his nearest approach to leisure. Many of last month's Notes apply to this.

Seed Sowing for the later crops will begin this

month. Spinach may be sown for an early fall-crop, but that to be cut later, or to be wintered over, should not go in until next month. Rutabagas, if not put in last month, should be sown at once; but the quicker-maturing sorts like Yellow-Stone and Aberdeen will be more sure now, and in the latitude of New York, are sown during the last of the month; the "Cow-horn" and "Strap-leaf" will do if sown early next month.

Beans and Peas.—If beans are wanted for pickling or salting, sow Early Valentine. Refugee is the variety usually advised for a late crop, but is not so good as the other for preserving or for table use. Late crops of peas will sometimes succeed. The Early Dwarf sorts, like "Little Gem," may be tried.

Onions are usually ready to harvest at the end of this, or the first of next month; when a majority of the tops fall over, growth has ceased, and the onions may be pulled. Many growers prefer to sell at once. If they are to be stored the onions should be left on the bed, throwing three or four rows into one, until well cured.

Onion Sets, as soon as growth ceases, are to be pulled, allowed to dry, and stored in a cool, airy place in thin layers, to prevent heating.

Celery.—Late plantings may still be made, and in ordinary seasons will form good-sized roots. That already out needs to have the cultivator run between the rows, occasionally, and such weeds as appear in the rows removed by hand or a "lance-headed hoe."

Root Crops of all kinds should be worked until the growth of leaves prevents it.

Sweet Corn in the garden, with a little care, may be made to aid the dairy. So soon as the ears are off, the stalks may be cut to feed green, or they may be cured for later use. Reject and burn all stalks that are "smutty."

Sweet Potatoes are to be kept clear of weeds until the vines cover the ground; lift or move them occasionally to keep the vines from taking root.

Squashes, on the other hand, should be allowed to take root. (See last month on insects, etc.)

Melons may be made to ripen evenly, by turning, as they approach maturity, and it is well to place a wisp of hay or a shingle under them to keep them from the ground. When a melon is ripe the stem readily parts from the fruit.

Watermelons are known to be ripe by the sound they give when struck by the finger. A sound cannot be readily described, but a little practice soon makes it familiar.

Insects will be abundant and must not be neglected. As soon as turnips are up "the flea" will find them. Sprinkle air-slaked lime or ashes along the rows. Watch the tomatoes for the "worm," which can usually be traced by its droppings.

Flower Garden and Lawn.

The work here will be mainly that of keeping things in order. See last month's Notes on mowing lawns, and let the operation be governed by the condition of the grass and the weather....Stake Dahlias, Tuberoses, Gladioluses, Lilies, and such other plants as need this support....Insects are often troublesome; the abundant lice on Chrysanthemums may be treated to strong tobacco water. The caterpillars which disfigure lilies are to be hand-picked....Cut away flower clusters when faded, and remove all spent annuals....Bedding plants in lines or figures will need pinching to keep them at proper height, or to prevent the lines from becoming indistinct by plants growing together....If it is desirable to make cuttings of any bedding plants, do it while they are still vigorous.

Greenhouse and Window Plants.

The needed directions for these were given in last month's Notes....Whatever repairs are needed about the greenhouses or frames, should be done long before cool weather comes....Propagation of many plants may go on in a shaded house. Most roses will grow from cuttings of shoots that have well-formed buds in the axils of their leaves, and cuttings should be taken of such bedding plants as it is desirable to keep a stock of during winter,

and of such plants as have been turned out into the borders, and will be too large to take up in the fall....See that pots set out of doors are not exposed to full sun, as this will greatly injure the roots, and is often an unsuspected cause of bad health.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our daily record during the year, show at a glance the transactions for the month ending July 13th, 1878, and for the corresponding period last year:

1. TRANSACTIONS AT THE NEW YORK MARKETS.									
RECEIPTS.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.	Peas.	Beans.	Malt.
25 days this m'th	1,382,000	4,907,000	3,962,000	490,000	261,000	1,137,000	—	—	—
26 days last m'th	1,341,000	4,812,000	3,617,000	616,000	307,000	811,000	—	—	—
2. Comparison with same period at this time last year.									
RECEIPTS.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.	Peas.	Beans.	Malt.
25 days 1878.	1,382,000	4,907,000	3,962,000	490,000	261,000	1,137,000	—	—	—

Gold has been up to 101½ and down to 100½, closing July 13, at 100½, as against 100½ on June 13; 100½ on May 13; 100½ on April 17th; 102½ on Jan. 12; 103 on Dec. 12; 102½ on November 12; 103 on October 12; and 105½ on July 12 of last year....Foreign advices, as to Breadstuffs, have been more or less variable and conflicting in tenor, but toward the close deemed favorable to the export interest, while domestic crop and weather reports have been, on the whole, encouraging; though, in instances, less so than about the date of our last review. Receipts of Breadstuffs at the seaboard have been on a restricted scale, checked to a considerable extent by speculative influences in operation at the West. This circumstance has been against a free export movement. Nevertheless, business in Flour and Grain has been quite extensive. In Flour, mainly for home trade; in Wheat, Corn, and Rye, largely for shipment; and in Oats, chiefly for local use and on speculative account, though to a respectable aggregate for the French market. Prices of Breadstuffs have fluctuated frequently, and in several cases, widely—Wheat showing a further marked decline, but leaving off more firmly. The transactions in Corn at the extreme close were on a very liberal scale, on Friday, 12th July, exceeding 1,350,000 bushels, of which over 1,000,000 bushels were for future delivery. New Wheat, and new crop Wheat Flour, have been arriving more freely, and have been selling on arrival at generally low figures. The most important operations in new Wheat, however, have been in Choice Red Amber, and White, for future delivery, extending into September, and almost wholly to export buyers....Cotton has been less active, and quoted lower, closing irregularly....Wool has met with a readier market toward the close, and leaves off with more firmness. Provisions have been in more demand, but unsettled as to prices, closing more steadily....Hay and Hops have been in generally slack request at our quotations....Tobacco more active at unchanged rates....Rice brisker at stronger prices....Naval Stores and Petroleum in moderate demand....Grass Seeds dull....Groceries fairly active; Sugar and Molasses steady....Ocean freights have been moderately active, especially in the Grain, Petroleum, and Provision interests, but close lower....Grain rates by steam to Liverpool closed July 13th at 6¼@7d. (about 14 cents) per bushel; Glasgow, 7¼d.

London, 7½@7¾d.; Bristol, 7d.; Hull, 7½@8d.; the Continent, 9½@10½d.; by sail to Liverpool, 6½d.; London, 6½@7d. per bush. Flour to Liverpool, by steam, 2s. @2s. 3d. (about 50¢ @51 cents per bush.); by sail at 2s.; London, 2s., and by steam, 2s. 6d.; Bristol, by steam, 2s. 9d. @3s., and sail, 2s. 4½d. @2s. 6d. per bush. Provisions by steam to Liverpool, 30s. @45s. per ton. Butter, in refrigerators, 125s. Cotton, by sail, 15½d., and steam, 1½d. per lb. Grain, by sail, for Cork and orders, at 5s. 9d. @6s. 3d. per quarter (8 bushels), and to Continental ports, 5s. 6d. @7s.; and from Phila. for Cork and orders, 6s. @6s. 3d., and from Balt. for Cork and orders, 6s. @6s. 3d.

Bees.—The month's business has been full of disaster to dealers. A worse market than has been found the past month has never been known, and prices fell lower than we have any precedent for. The receipts have been large, and the demand both from butchers and for export has been small, and between the two, dealers have lost very heavily. Towards the end of the month lighter receipts gave matters a better look, but still the market dragged along, and purchasers did about what they pleased with the stock offered. At the close the

market again fell off ¼c. per lb., sales being made at 7½c. per lb. for Texans, to dress 55 lbs. per 100 weight; 8½c. for fair natives, 56 lbs. to the 100. The extreme price paid was 11½c. for extra steers of 1,635 lbs., estimated at 57 lbs. dressed weight on 100 lbs. live.

The prices for the past five weeks were as follows:

WEEK ENDING	Range.	Large Sales.	Aver.
June 17.....	7 @ 11 c.	8½ @ 9½c.	9 c.
June 24.....	7 @ 11½c.	8 @ 9½c.	8½c.
July 1.....	7½ @ 10½c.	8½ @ 9½c.	8½c.
July 8.....	7½ @ 10½c.	9 @ 10 c.	9½c.
July 15.....	7½ @ 11½c.	9 @ 10 c.	9½c.

Cows.—There has been no demand for cows, and to sell those which have been offered has been impossible at any price. Milk from the country has sold as low as \$1 per 40 quart can, and city dairies have no inducement to buy cows. There are no prices, and quotations are nominal.

Calves.—The demand has been good for veals, and with a short supply trade has been active, and prices tending upwards. Naturally, things took a turn, more stock came forward, and the market, uneasy all over, declined at least ¼ ct. per lb., with a dull feeling. The closing market was weak, with sales of buttermilk calves at 3c. @3½c. per lb., live weight. Veals brought 6c. @6½c. for good to extra, dead weight. Grass calves were as low as 4c. per lb., dressed.

Sheep and Lambs.—A gradual improvement has marked the course of trade in this stock. The supply has been fair, the quality good, and the demand strong. Prices advanced up to the end of the month, when trade became weak, and prices declined. A falling off is to be noted as we close our report, and a range of prices from 4½c. @5½c. per lb., live weight, with 5½c. @6½c. for lambs.

Swine.—Hogs have been steady, without much change in prices. The final quotations are 4½c. @4¾c. per lb. for live hogs, and 5½c. @6c. per lb. for dressed, with a firm market.

The Horse Market.—The supply of horses the past month has been less than usual. At the same time trade has been very quiet. Over 2,000 head have been exported so far this year. In Europe the horse trade is very much depressed, and the now almost certain prospects of peace have not tended to change this feeling. There promises, however, to be a steady demand for useful horses for the "tram-roads," as the car routes are there called, and it is to be noticed that our thoroughbred horses are coming into favor there. Quotations are nominal, city business being entirely suspended at present.

"Big Head."—"A. V. C." Pensacola, Fla. This is a disease of the bones of the head, and consists of a spongy growth of bony matter, which not only injures the jaws or the skull, but causes tumors and abscesses in the muscular covering. As these abscesses have their origin in the diseased bone, they can not be cured by any direct treatment of them alone. The diseased bone must be cut away. As it is obvious that, to remove the bone of the skull or that of the jaw, would seriously affect, if not fatally injure the horse, this disease is classed among those which are incurable, except through a favorable natural action by which healthy bony tissue may be deposited, and the disease cease. The trouble is constitutional, and scrofula is generally the predisposing cause. No amateur treatment can be recommended. The advice of a competent veterinary surgeon should be sought. We are aware that such advice as this is difficult to get, but it is to be hoped that it may not be many years before skilled veterinarians may be available, and that their need will be recognized.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the American Agriculturist, containing articles referred to in the "Basket" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.60 per volume.

The Latest Crop Reports to this date (July 16) are generally very good. The fears that the open, mild winter, and early, warm spring would be followed by a cold, wet summer, have not been realized. The hot weather during the last of June and the fore part of July, was just what the corn-crop wanted, to push it ahead rapidly, and, with the large acreage, the yield will be very great, if it is not cut down by unusually early frosts. The favorable weather also helped to filling out the wheat at the North, where it was not ripe. The later rains of the second week in July, while interfering with wheat-gathering somewhat, came just in time to avert the parching effects of the hot spell. Thus far, we have every indication of considerably larger yields of the great staple crops even than last year, taking the country as a whole; there are exceptional places where storms, insects, worms, etc., have injured the crops. These magnificent crops, while tending to lower the prices per bushel to be obtained by the producers, yet furnish a fair income from the large quantity, and an abundance of cheap food will help out manufacturing and other pursuits, and tend to set in motion the wheels of industry generally; more products to be moved by railways, means more iron to be used, and more manufactured products to be consumed. This wealth from the soil will tell strongly towards a recovery from the depression of the past five years. Our wheat and corn, however abundant, cannot sink in price below a certain figure, for the lower the price, the greater will be the foreign demand, as well as the larger the consumption in our own country, which will prevent any disastrous fall in prices.

Railroad Crop Reports.—The Chicago and Northwestern Railway Company has inaugurated a most important system of gathering accurate reports of the condition of the leading crops, from the hundreds of stations along the great extent of road it owns or operates. The strict discipline among railway employees, enables the managers to gather very complete and systematic reports, and it is desirable that every principal railroad running through agricultural regions should adopt the practice. From the reports of the C. & N. W. R. R. for the early part of July, we learn, that from 266 stations where wheat is the main crop, 102 report the wheat above the average of last year's large yield; 126 report it as good; and only 38 as not so good. Of 273 stations where corn is the main crop, the acreage reports from 139 stations are larger than last year; 133 about the same, and 1 below. Of its condition, 12 report it better than last year, 155 as good, and 106 not as good. The recent hot weather has doubtless greatly improved the corn crop generally.

A Selection of Roses.—A correspondent in Iowa, apparently a beginner in business, asks us to give a list of the best "Hybrid Perpetual" roses, the best white, the best crimson, the best climber, etc. He says that "the American Agriculturist" has been worth a small fortune to me; and though we are desirous of aiding so appreciative a correspondent, he has proposed a very difficult task. The rose catalogues number thousands of varieties, and each year twenties, if not hundreds, are added to the list, hence, to give a list of "the best," is a matter almost impossible to one who is not a "rose fancier." We can perhaps help our friend by giving him a list, if not of "the best," of really good sorts. The name "Hybrid Perpetual" is a thorough misnomer—so far as the "perpetual" goes, and if we wish a succession of bloom, during summer and autumn, we must take China and Tea roses, which are not usually hardy. These are generally smaller in flower, and of less vivid color than the others, but they bloom almost continuously. As to the "Hybrid Perpetuals," for which the better name is "Remontant," we should for six, well established and standard kinds, take *Baronne Prevost*, pink; *Charles Lefebvre*, reddish crimson; *General Jacqueminot*, richest crimson; *Madame*

Lacharme, white, with a blush of pink; *Madame Victor Verdier*, brilliant earmine; *Paul Neyron*, rose, and of great size. We might go on and pick out other sets of six, but we should not like to be without either of the above. As to the best white rose, perhaps *Madame Planter* will give most general satisfaction. It is classed as a "Hybrid China," is with us perfectly hardy, and though the flowers are not very large, they are in great abundance. Several climbing remountants have been offered of late years, which we have not tried. The best climber we have is *Queen of the Prairies*, for vigor and abundance of bloom, but the *Gem of the Prairies*, fairly vigorous, is fragrant, and on that account preferred by many. As to crimson, *General Jacqueminot*, already mentioned, is one of the reliable sorts; it is not so double as some, but a free bloomer, and most brilliant. We advise our Iowa friend to get the catalogues of those dealers who make a specialty of roses, and to test those varieties which promise to be hardy in his severe climate.

Agricultural Education at the Mass. Agricultural College, has at last been placed practically on the basis of free tuition by a recent action of the trustees, who voted "that each graduate [of which there are now over 150] of the institution be allowed the privilege of nominating one student to a free scholarship for the full course of four years." A friend has also offered to pay the tuition for the course of every worthy student presenting himself for admission to the next class, who shall meet the requirements as to scholarship, etc. The expenses of living have also been so reduced, that the cost to those having the scholarships need not be over \$150 a year, a portion of which can be earned by work upon the farm. A farmer's son, or any young man who desires to get a good agricultural education, has in these offers an exceptional opportunity. Applicants should address President W. S. Clark, Amherst, Mass.

How to Carry a Watermelon.—We feel very sure that when a thing is really needed, it will be supplied by some inventor. No one article in the market is more unmanageable than a watermelon. There was no difficulty in raising watermelons in Florida and Georgia, no trouble in placing them on sale in New York—and good melons too, by the way—at about the time that people in the vicinity were putting in their seeds. Melons were easily raised, easily transported and placed on sale, but there was a great obstacle to selling them, and that was in the melon itself. It was too large for the average basket, too troublesome to carry under the arm, and though it might be easily carried on the shoulder, the people would not "tote." In short, there must be an easy way of carrying melons, or they must remain unsold. Last season melons were offered, lashed with tarred spinn yarn, evidently the work of sailors; this helped somewhat, but this year the fruit has appeared, furnished with a regular handle. Evidently the idea was borrowed from the now popular shawl-strap. At all events, some genius has hit the popular want, and supplied what nature failed to do, a handle, by which the watermelon can be as easily carried as any other parcel. The essential part is the handle made of bass wood. This has a sufficient supply of strong twine, and two "beckets" of the same wood to distribute the pressure.

When the melon is harnessed and ready for travel, it appears as in the figure. We have more than once said that the raising of vegetables and fruits was a small matter, as compared with the proper selling of them. Some genius, by means of this simple contrivance, has greatly facilitated the selling of watermelons, and has thus added to the value of many acres in the Southern States.

About Preserving Green Corn.—We have several times stated that we knew of no method of *canning* green corn that was practicable in families. Mrs. C. C. R., who writes a very pleasant letter, thinks we are in error in this, and sends us her method, which is not in the proper sense, *canning* at all, but a method of *pickling*. By *canning* fruits or vegetables of any kind, we understand the putting of them up by the thorough exclusion of air, with sugar, salt, or other seasoning sufficient to make them acceptable when eaten; but which has nothing to do with their preservation. Mrs. R. uses

tartaric acid, which is really *pickling* the corn, just as other vegetables are pickled in acetic acid, or vinegar, but it is not *canning* the corn in the proper sense of the term, or by the method followed by those who put it up for market. We have, in former years, given the method of preserving green corn by means of salt, and also by the use of tartaric acid, but as this last was several years ago, we give Mrs. R.'s method, with the remark that it has been commended to us by several other housekeepers, though we never happened to try it ourselves. It is really *Pickling Green Corn in Tartaric Acid*. Mrs. R. says: "Cut the corn from the cob, and cook it in a plenty of water for about 5 minutes. To every 6 quarts of corn (measured before cooking or adding water) add one ounce of *Tartaric Acid*, dissolved in a little water. Put the acid in while cooking. Dip into the cans, and seal immediately. It will keep for years. To prepare this for the table, pour off the sour water (which is to be saved), and put in fresh cold water. To a quart of corn add half a teaspoonful of soda, and a teaspoonful of sugar. If you should add too much soda, the corn will turn yellow. In that case, add enough of the acid water (to be saved for the purpose) to turn it back again to the proper color."

A Rustic Chair, Easily Made, and quite ornamental, in even a small lawn or yard, is here illustrated. The sketch is from a chair we saw on the grounds of Dr. R. S. Bacon, at Finsling. It is most durable if made of cedar, but any wood will answer. The main piece is a pole say $4\frac{1}{2}$ feet long, $3\frac{1}{2}$ to 4 inches in diameter at the base, and an inch less at the top. This stands inclined 25° to 30° from a perpendicular. Three other short pieces nailed upon it, supply the necessary legs or supports. The other round sticks are added as shown. The seat has four side-pieces, filled in with the parallel pieces which are nailed to the front and rear border piece. The side pieces come forward far enough to supply arm rests. The whole is made of round, undressed limbs, or small saplings, nailed together. A hatchet to cut the sticks, with hammer and nails to fasten them together, are all the tools needed. Any smart boy can put together a trial chair, on a rainy day, and afterwards make up as many as he chooses from any wood.

Remarkable Shooting.—On July 13 we witnessed for an hour the shooting feat of Dr. W. F. Carver, who during 7 hours and 38 minutes (or 8 hours and 10 minutes, including resting spells), fired 6,212 times at glass balls flying in the air. Of these he hit and broke 5,500, and missed 712. He attempted to break the 5,500 glass balls in 500 minutes, and accomplished it in 489 minutes (11 A. M. to 7:30 P. M.). The wind blowing from the front drove much smoke into his eyes, causing many of the misses. Those present at the finish say he seemed to suffer no inconvenience from the effort, except that produced upon his eyes by the smoke. The glass balls were $2\frac{1}{2}$ inches in diameter, and filled with feathers, which flew out in all directions, as the balls were broken. They were tossed up by hand 20 to 30 feet in front of him, and each ball had to be aimed at and hit on the fly, with a single bullet (not with a handful of shot), and between each shot the gun was lowered, the old shell thrown out, and a new one inserted, and the gun then raised and aimed. We noted several instances where 16 shots were fired in 19 to 24 seconds. As the loaded rifle weighs 10 lbs., the raising of the gun 6,212 times was equivalent to lifting 62,120 lbs., or 31 tons. The strain upon the eye and nerves of taking sight so many times must have been very great. This experiment shows the power of endurance which the human body and mind are capable of, and in this respect is interesting. It can be of little practical utility for others to learn to shoot on the wing with the rifle.

Another Clover-Weed Seed.—On p. 103, March No., magnified engravings are given of the seeds of the weeds common in clover in this country as well as in England. It is there remarked that some of the commonest weeds of the English clover fields are scarcely known here, while we have a number of pests unknown in England. We expected that the article referred to would cause our readers to look sharp to their clover-seed, but some have anticipated us, and long before the article reached them, several have forwarded us samples of clover-seed, to inquire as to the foreign seeds mixed with it. Two or three of these samples contained a

small flattened, shining black seed, shown in the engraving here given, of the natural size, and magnified. In one case the clover contained so much of this as to attract the attention of even the most careless. The seed is evidently that of one of the "Knot-weeds," or *Polygonum*. The genus *Polygonum* is a large one, and includes species very unlike in appearance, from the little "Knot-grass," or

"Door-weed," (*P. aviculare*), round in almost every yard, up to the showy "Ragged-sailor," or "Princes' Feather," (*P. orientale*), often seen in old gardens, and growing 5 to 8 feet high. Other well-known species are the acid "Smart-weeds," or "Water-Peppers," of which two are common in moist places. Another very frequent weed in fields and gardens, is a branching species 2 feet or more high, with a usually reddish stem, and leaves shaped so much like those of the peach that it is named *Polygonum Persicaria*, and is known in England as "Persicary," or "Peach-wort," but with us, on account of a large blackish spot (usually present) in the center of each leaf, as if it had been pressed by an inky thumb, it is in this country usually called "Lady's Thumb" and "Black Heart;" its small greenish purple flowers are crowded in close oblong spikes at the ends of the branches. Besides this, there are three other species of a very similar habit and aspect, and only distinguished from this by botanical characters, which we need not give, for so far as the cultivator is concerned, the plants are practically alike. All have similar seeds, though differing in size, and some minute particulars, but they are sufficiently like the seed here engraved, (which is apparently that of *P. Persicaria*), to allow them to be recognized under the *American Agriculturist* Microscope. They are all annuals, and on that account less to be dreaded than some perennial weeds. But they are *weeds*, and will, if each one gets a start, occupy the place that belongs to a clover plant. For this reason, clover-seed that contains *any other seeds* than clover, is to be regarded as foul, and should not be sown. It is true that there is a choice of evils, and these weeds are of little importance as compared to "Viper's Bugloss," Toad-Flax, "Canada Thistle," and others. Still they rob the crop of nutriment, and rob the farmer by occupying the land unprofitably. *Sow clean seeds.*

Basket Items continued on page 313.

Sundry Humbugs.

In our warnings against humbugs, we have confined ourselves to those practised upon the community in general, and especially upon the agricultural or rural portion thereof. By doing this, we leave the field of special humbugs untouched, for there is hardly a general occupation or trade that is not afflicted by its peculiar frauds. In investigating the various humbugs we are brought in contact with local as well as United States officers, from whom we sometimes learn new and special forms of rascality, but as they do not, as a general thing, affect the readers of the *American Agriculturist*, we do not mention them. Among the specialties are the various tricks played upon

KEEPERS OF HOTELS;

indeed one of these has become a regular thing with a certain set of sharpers. As keepers of hotels, especially in small towns, are farmers also, and a good number of them are readers of the *American Agriculturist*, we give an account of one which has recently been the means of swindling many inn keepers, especially in the Western States. Scene, a hotel in a small town—but a flourishing town—in Illinois. A young man arrives, calls for the best room in the house. He enters his name in a bold hand on the register as Turner, of the jewelry house of "Smith & Co., New York. Manufacturer at Providence, R. I." The first thing he asks for is letters; finding that there are none, he particularly inquires of the times for the arrival of the mail, as letters of great importance were

to meet him there. Has had a dusty ride, it is some time before the dinner hour, and he orders a bottle of the best wine in the house; he does not like to drink alone, and the landlord must help him dispose of the bottle. The young man's chief want seems to be letters, and all the next day he asks at every mail's arrival for letters. At last the looked-for letter comes, he hastily opens it in presence of the landlord and takes out a check. He curses the stupidity of the cashier of the house in New York. "He might have known that there was no bank at this place. I charged him to always send money in a registered letter, and here is a confounded useless check (for \$100 or \$200, as may be). I am notified that a case of samples are sent to — (the next town), where I must go at once, and here I am with nothing but this check." And more of the same sort. The landlord is good-natured, the young man is good looking, and free with his wine, and the chances are that the landlord ends the young man's trouble, and offers to cash the check—minus the young man's wine and board bill. Young man is very grateful, gets his check cashed, and starts to the next town for his samples. But he does not stop there, he goes on to some other place, as may have been agreed upon, where the same game is played over again; the same anxiety about letters; the same disappointment at receiving a check instead of money, in a town where there was no bank, etc., etc. As the checks are drawn on some New York Bank, it is a number of days before the landlords discover that they are mere worthless paper, and the young man, who, of course, never goes where he says he is going, is far out of reach.

A LARGE NUMBER OF LANDLORDS

in the Western States hold the worthless checks of "Smith, Melville & Co., Manufacturing Jewellers in New York; factory at Providence, R. I." But of course the name is changed from time to time. We have some of the checks, and can say that, taken as checks, they are very pretty.... Here we have again

CLARK & CO. WITH A NEW NAME.

In some branches of science there are books giving synonyms, or the different names by which an animal or a plant has been called. We shall soon need such a list for Clark & Co.; it would include Russell & Co., Hetheridge & Co., Keyes & Co., and we now have to add W. P. McCall, who hasn't a bit of a "Co." to his name. But W. P. still sends out the same persuasive circular headed "A Decision at Last," and informs people that they can get "One lot of Gold Jewelry (60 Different Pieces), valued at \$220.00," and that "the percentage due is \$11.00." W. P., that, in these hot days, is a little too much for such jewelry as yours; seventeen cents apiece for Jewelry things! We can go down into the back woods of Maine and beat you as to price. No wonder your concern changes its name so often if it asks so much for Jewelry. One of our friends at Seekonk, Mass., is not a little indignant that W. P. McCall should have sent him—who never bought a lottery ticket in his life—a circular pretending to adjust some old lottery claim. This is nothing to the case of one of our friends, who is one of the most steady and steady going of the Society of Friends, who received a letter asking if a certain signature was his, and if so he was entitled to certain mining shares! It only shows that these chaps who buy their old letters by the thousand, for the sake of the signatures, are liable to occasionally "wake up the wrong passenger.".... The circulars of that

CINCINNATI ART CONCERN

now begin to come in from the Pacific coast. We can only say to our friends there, as we have to those nearer home—Don't. These people profess to have had a "drawing," and anything that looks like a game of chance should repel all right-thinking people. The pictures said to be drawn, are sent for a charge for packing, and there will be the express charges to Oregon, etc., besides. We feel very sure that nothing can be sent under these terms worth paying the freight charges on.

THE NON-EXPLOSIVE POWDER CHAP

is around in Central New York with his stuff to put into kerosene lamps to prevent explosions. It seems that this humbug is not dead yet, though we several years ago showed that the powder was only common salt, colored with a little Prussian blue, or cheap ultramarine. It can have no possible effect upon oil, and if it induces people to use poor and cheap oils, it is murderously dangerous. The only safety is in good oils and good lamps. Nothing can make poor oils safe.... A Vermonter saw in a leading agricultural paper an attractive advertisement of

"CRYSTAL GLASS GOBLET,"

which he ordered. After much delay, he received a half dozen, costing him, including express charges, \$2, and he found them such goblets as he "could buy at any store for a dollar a dozen. He thinks it very wrong for the paper to publish such an advertisement. We think so, too; but as the advertising columns of our own paper are all we control, we don't see how we can help him. ... We have had occasion to refer to the

NOVELTY CATALOGUES,

so called, in general terms, but to specify these would but serve to advertise them. Some of them are pamphlets of 30 or more pages, and offer a remarkable lot of articles, some of which are mere toys, or harmless enough, but intermingled with these—and hardly concealed by them—are offered things of the most pernicious character. For example, in a publication of this kind now before us, we have offered: "Spy-glasses, an article valuable to every farmer;" next, several trashy hooks, and then "Transparent Cards," which it is not necessary to describe to those who know what they are, and those who do not know them, get a very broad hint in the information that the pictures "are of such an intensely interesting character that our agents retail them at fabulous prices." Every possible trick is resorted to, to get the addresses of school-children of both sexes, and they are then plied with advertisements of the kind above quoted.... Here is a letter from a lawyer in Washington Territory, from which we infer that one of his clients has received

"A PACKAGE OF JEWELRY"

from one of the many dealers in the bogus article in New York. The lawyer asks us to investigate the matter, and if we find the concern to be, as he believes it, a fraud, to expose it.—No, we thank you. It is altogether too hot weather for us to go up towards Union square, to learn what we already know. We know that a concern that sends jewelry to one who has not ordered it, especially of that kind which sells for \$30, and will bring at retail \$135, need not be looked after. It is an old dodge. A bogus jewelry chap on Broadway sends to J. A., in Washington Territory, a parcel by express. J. A. receives parcel, pays charges on it. In due time a bill comes, which J. A. does not pay. After a while comes a shyster lawyer, to collect the bill; he can prove that J. A. took the parcel from the Express office; the presumption is that he ordered it, and the chances are that he will have to pay for the stuff. The only safe way is, not to receive packages from the Express, unless one has been previously notified of their contents. We are informed by an officer of wide experience that some of the subordinates in the Express offices—well, to say the least—do not try very hard to prevent such swindles as these of forwarding packages of jewelry to those who have never ordered them—Moral:

SCRUTINIZE ALL EXPRESS PARCELS

with care.... So many letters on medical matters had accumulated that we last month treated them in a special article on "Medical Matters," and so

ON GENERAL PRINCIPLES,

we advise every young man who thinks he has some trouble—we say, "thinks," for such troubles are largely imaginary—to let alone an "doctors" and combinations of doctors calling themselves "Institutes," and advertising to cure such troubles. We do not know that all are equally vile, but we have known of cases in which chaps, calling themselves "doctors," and "Institutes," have threatened to expose young men with unfortunate, but not immoral troubles, to their families and friends, except for a certain weekly pay. Any one who advertises to cure any particular disease, at once cuts himself off from all fellowship with regular medical men, and is an outcast from the profession. Have nothing to do with such, whether they are banded together, or prey singly on the unsuspecting, but go to some real physician, in whom you can have confidence, and let all advertisers thoroughly alone.... Abbey, the Buffalo quack, who has, under pretence of sending a

PUZZLE PICTURE,

succeeded in bringing his nasty book to the knowledge of decent people, claims to have sent out millions of his "Toll-gate" pictures. His dodge is to offer a "puzzle picture," and family and religious papers have advertised it, apparently without question as to what it would lead to. A very coarse "puzzle" picture about the size of an ordinary envelope is sent, and on the back are the announcement of books and medicines, such as no decent person has any need of, and which young persons need know nothing about. The chap is out with a new picture, which he sends to every post office in the country for distribution. The P.M. at a small office in Massachusetts writes that hundreds have come to his little office in packages of 25 or 30, with a request that they be distributed. We are glad to know that there is one Post Master—no doubt there are hundreds more—who will not engage in any such dirty work.... "A Victim" in Penn. writes that he has taken half a dozen bottles of some

"ANTI-FAT" COMPOUND,

with a view to reduce corpulence, and that while taking the stuff he has gained just ten pounds! and asks what he shall do. Evidently one thing to do is to stop taking the stuff. He may, no doubt, find useful hints as to diet and exercise in Banting's work on Corpulence, which has been reprinted in this country. Our general advice, to take no secret compound whatever, applies here....

We thought that the medical part of our budget was of a rather tame kind—but we were wrong. Here we have that in "The Little Blue and White Book," which we only before had in a poor shabby black and white circular. It is:

"NARROW ESCAPE FROM DEATH.

TRUTH STRANGER THAN FICTION—(If we mistake not that has been mentioned before)—THE TRUE HISTORY OF UNOKAS PILINDIAS. That is all on the "Kiver" in blue and white—and very pretty it looks. We read on the first page on the inside "Truth Stranger than Fiction," which we insist is not an original remark, and "Mistaken Identity of a Disease we are all subject to. How, after two years of suffering, the Patient was cured by an INDIAN SQUAW"—it is a touching story, and we have already told it in these columns. Like all such stories it has its moral, which is, take "Unokas Pilindias and Live"—or "Neglect them and Die." It is too hot this July night to think which we will do, but as for Unoka, "Inventor of Unoka's Pilindias," of whom a portrait is given, she looks as if, had she turned her hand to it, could do a powerful amount of washing. But on the last page of the cover we have a portrait—not of Miss Unoka Pilindias again, but of her arm only. We know it is hers, not only because it is so labelled, but from the big development of muscle, which could only come of washing; that arm has a hand, and that hand squeezes five snakes, such as were never seen before: She has an awful power of squeeze, and the way she makes them snakes spout fireworks is just stunning. There is a most pathetic appeal on the last page of this pamphlet to "Dear Reader":—the writer believes, or says he does, that should we have "any of the complaints referred to in his little blue and white book, we will give Unoka's Pilindias a trial"—to which we say most assuredly not. We shall avoid, and advise all others to avoid all such out-and-out quackery.

Oleomargarine and the Butter Market.

—It is worth while for dairymen to consider whether present low prices of butter and cheese, are influenced by oleomargarine. Years ago the *American Agriculturist* pointed out the certain result of its competition with honest butter and cheese; viz., lower prices and difficulty of sale. Now the truth of the statement is apparent, and even the gilt-edged product of the dairy, which cannot be produced for less than 50 cents per pound, goes a begging at 25, while the "Dairy Company's" product, oleomargarine, butterine, and other compounds of rendered fat and soiled milk, are driving true dairy butter out of the market. Well, perhaps dairymen have none to thank for it more than themselves. Their leaders in conventions, have glorified and advertised this stuff; professors have "assayed" upon it, and have proved in the very teeth of its natural opponents, that it was really as good, if not better, than genuine butter; that it possessed all its virtues, and none of its faults; while dairymen stupidly let this thing go on, and permitted the oleomargarine men to flich away their markets, and customers. If dairymen have been willing, who shall say nay? but on behalf of the innocent consumers, we continue to protest, and shall continue, while waste fat is palmed upon them for pure butter.

The Beet-Sugar Industry of France.

In 1824, France produced a total of 15,000 tons of beet-sugar, in over 100 factories. In 1837, the product was 49,000 tons. France, since that time, has doubled the product of beet-sugar every ten years. In 1820, the product was only 2 lbs. for each inhabitant; in 1865, it was fourteen pounds per capita. Since 1865, except in the immediate vicinity of the seaboard, no sugar is seen or used in France except the beet-sugar. The same is true of Germany. This is almost the only sugar used in Paris, Vienna, Berlin, Dresden, Leipsic, or Munich. In 1837, the yield of beets per acre was twelve tons; price \$3 per ton. In 1865, the yield was sixteen tons per acre; price \$3.25. The percentage of sugar contained in the beets, in 1837, was 10 per cent; in 1865, 11½ per cent. The cost in 1837 was 7 cts. per pound; in 1865, it was reduced to four cents per pound. Thus, it has required nearly a half century to establish this great and valuable industry on the Continent of Europe, on such a basis as to defy competition, and we now have the benefit of their experience. It has been the result of careful and continued attention to thus increase the product, as well as the percentage of sugar in the beet, and this by studying carefully its natural laws, and by the application of chemical knowledge and mechanical ingenuity to extract the sweet therefrom, to purify it, and render it suitable for the most fastidious tastes. This sketch, while relating mainly to France, applies also to the rest of Continental Europe: France only led in the race. Such is a brief history of the growth of the

industry up to 1865, and since that time its continued success is shown by the following statistics: Total product of beet-sugar in 1853, 200,000 tons; total product of beet-sugar in 1863, 452,000 tons; total product of beet-sugar in 1873, 952,000 tons. It may be considered as one of the established industries of the temperate zone, and only awaits the judicious application of capital and labor to establish it on any suitable soil, and in any proper locality. The permanent effects produced on agriculture in France by the cultivation of beet-sugar have been astonishing. In the cane-sugar districts, no other crop is to be seen, while cattle, sheep, and hogs are few. In the beet-sugar districts of Central Europe, on the contrary, the fields are crowded with the greatest diversity of crops, such as beets, wheat, rye, oats, barley, etc., as well as all of the cultivated grasses. No farmer there need to be told which system is the most enduring. On a great public occasion, the following significant inscription was placed on a triumphal arch: "Before the manufacture of beet-sugar, the arrondissement of Valenciennes produced 695,590 bushels of wheat, and fattened 700 oxen. Since the manufacture of beet-sugar was introduced, the arrondissement of Valenciennes has produced 1,157,750 bushels of wheat, and has fattened 11,500 oxen." A farm of 832 acres in France, the product of which, with the ordinary farming, amounted to \$5,000 per annum, with six years of beet-sugar cultivation, produced \$41,200 per annum. Another farm, of 295 acres, produced 5,225 bushels of wheat, 2,500 tons of beets, and fattened 150 head of cattle, per annum. The farmers attributed their success as cultivators entirely to the immense amount of barn-yard manure, which the beet-pulp gives to the stock, enabling them also to effect an improved condition of the soil. The improved and increased amount of profitable culture of the land consequent upon beet-culture is now universally acknowledged, and wherever the beet is cultivated, lands advance in value, and wages take the same direction. Cows fatten upon the leaves and pulp, and also produce more and better flavored butter and milk than when fed on grasses; so that the production of sugar from the beet adds to the supply of bread, butter, and meat; and these—the leading necessities of man's existence—stimulate and aid each other.

Varieties Used—Harvesting and Storing the Crop.

The varieties of sugar-beet most extensively used are the White Sugar, or Silesian, the Imperial, and the Quiddlingburger, and they penetrate the soil from eight to twelve inches. The most desirable weight is from 1½ to 4 pounds each. Their greatest diameter is from three to six inches. Large or overgrown beets are very poor for sugar. If the soil is cultivated to a suitable depth, the beet-root will grow entirely beneath the surface; but when the ordinary cultivation is used, being unable to attain its length below the surface, it will extend above the ground; where, exposed to the sun's rays, it is injured, and less productive. Any soil that is suitable for wheat, which has been under cultivation—the longer the better—that admits of deep tillage, clear of stones, with a clay tendency, is suitable for beets. The soil of Maryland is well adapted for growing beets, and, in fact, many parts of nearly all the older States of the Union; and the industry ought to be generally introduced into this country at an early day.

AN OLD FRENCH FARMER.

Some Bee Notes for August.

BY L. C. ROOT, MOHAWK, N. Y.

Since the writing of July "Notes," the outlook for beekeepers has assumed a much more encouraging aspect. The very warm days of the last of June and the first of July, have, in a degree, retarded the rapid gathering of honey. During extremely warm weather, great care should be taken to ventilate each hive, and to keep the apiary shaded from the direct rays of the sun, as the combs are liable to be melted down. Follow directions given last month, and remove box-honey from the hives as fast as the boxes are well filled. In localities where buckwheat and other late forage abounds, the boxes removed may be replaced with empty ones. Each beekeeper must learn the honey resources of his special locality, and not continue adding boxes too late in the season, as the boxes may not be filled, and hence may get soiled and unfit for use. After removing boxes, the bees may be driven from them with smoke; or the boxes may be placed in an empty hive, box, or barrel, and a cloth thrown over it, leaving a slight opening at one side, where the bees may pass out and return to their hives. Box-honey should be examined occasionally, to see that the moth-worm is not injuring it. If only a few are found, they may be removed, but if badly affected, the worms should be killed by placing the boxes in another box, and smoking them with brimstone. Care should be taken not to extract the honey from the body of the hive,

so late in the season that the bees can not gather a sufficient amount to winter upon. Allowing bees to swarm late is often objectionable for the same reason. We should have the requisites for successful wintering in mind, even at this time of the year.

HONEY YIELD.—I have selected a very strong swarm of Italian bees, and have given it very particular attention, furnishing extra combs from time to time, and, in fact, have endeavored to secure the most favorable conditions in every respect. At present, it contains thirty-two (32) movable combs. I propose to extract the honey from these combs, with the honey extractor, during the entire season, returning the empty combs to be refilled; and will report dates and amount of honey taken at each time for the benefit of the readers of these "Notes." The first honey was taken July 5th, amounting to 90 lbs.

How the Fourth was Celebrated at "Houghton Farm."

Those who think that the national holiday can only be properly celebrated by going somewhere—anywhere away from the farm, and that a plenty of powder and punch are necessary to a proper enjoyment of the day, may take a hint from the manner in which the last Fourth was celebrated at "Houghton Farm." This farm is a beautiful spot among the mountains of Orange Co., N. Y., and is likely to be heard of hereafter by the readers of the *American Agriculturist*. Suffice it to say for the present, that, taking all its departments together, a goodly number of hands are employed, the head farmer, and some others, having families upon the place. The Celebration was quite impromptu, and owed its success to the heartiness with which all entered into the scheme. There were the proprietor, his family, and his guests (of which the writer was one), and the various farm hands, conspicuous among whom was the head stable-man, the prime mover in the out-door sports, one and all bent upon having a good time—each one being desirous of doing something to help. Where such a spirit prevails, each desirous to please, and of being pleased, the rest is not difficult. The very near neighbors were invited, and as those farther away had wind of the doings, there was, by 4 o'clock, quite a large assemblage in and around the field where the first performances took place. Friendly clouds made active exercise tolerable, and the young men, encouraged by prizes, which ranged from small sums of money, to "the makings" of a corduroy suit, entered into the sports with a will. First came a game of "Blind Man's Buff," in which each blinded man had a straw-stuffed canvass club, with which he was to hit one of the number who was not blinded, and he carried a bell as a guide to his whereabouts. There was, of course, much hitting of every one but the right one, and much amusement was afforded. Then there was a foot race of 100 yards, in which length of leg plainly told. In contrast came a sack race, wherein a dozen, each with legs and arms confined in a sack, started, while but few, on account of tumbles, reached the mark. Next there was diving for a coin at the bottom of a tub of water, the winner to fish it out with his mouth. This, which made great sport, was followed by a wheel-barrow race, in which the blind-folded contestants showed much skill. The last, and most amusing race was of 25 yards, each one carrying a pail of water on his head; the one who had the most water in his pail on reaching the goal, being the winner. There was of course much spilling of water and wetting of clothes, but there was much fun also, and those who came in the wettest seemed to laugh the most heartily. The contestants in these games, and others, were considerably supplied with iced "switchel" (molasses and water spiced with ginger). The crowning portion of the out-door sports was a tub-race, participated in by three guests at the farm. This took place in Awassema Creek, and, like all such races, was a series of false starts and complete duckings, which, though exceedingly laughable, need not be recorded. Suffice it to say that a gentleman connected with the *American Agriculturist* is the happy possessor of a genuine tin cup, as a mark of his prowess in the tubby line. The tub-race ended the daylight amusements. In the evening there was another gathering in front of the dwelling house, where a part of the broad veranda had been enclosed to form a stage for the exhibition of shadow-pictures and tableaux, which were presented by the members of the family and visitors to an audience which included those who had taken part in the day's sports, and the neighbors. The most pathetic history of Mary Jane, and other things, were effectively shown as shadow-pictures. Songs were sung. The lady of the house read the old story of Geneva, but ever new as told in Rogers' verse, as a prelude to a beautiful tableau picture of a bride. The appearance of one of the young ladies as the Goddess of Liberty excited much enthusiasm, which found vent in the singing of the "Star Spangled Banner" by the company. At length the "Flower of the Family"

appeared with a "good night" candle, when the audience left after singing "America," and showing their appreciation by hearty parting cheers.—Here was a celebration which was enjoyed by many, brought no risk of fire, and did not cost one-twentieth of what is usually spent in fizz and bang. It was extemporized from materials at hand, and with the desire to please and readiness to be pleased on the part of all, was a real success. We give this brief account of it, that those who may next year be puzzled to know "what to do on the 4th," may profit by the hint; for such a completely successful, really pleasing, yet quite inexpensive and thoroughly harmless celebration as that at "Houghton Farm," is possible on many a farm throughout the broad land, and if not always practicable upon a single farm, a neighborhood celebration may be carried out upon the same plan.

Thinning Roots.—The yield of roots, as well as their feeding value, depends largely upon a proper thinning of the plants. Large roots are by no means worth the most. In an experimental crop, grown in England, small Swede turnips which yielded 20 tons per acre, were found to contain as much dry substance as large ones which yielded 40 tons per acre—the excess of 20 tons being wholly water. The small plants were thinned out to a few inches apart; the larger ones to 14 or 16 inches. As the thinning of root crops should be done at once, these facts are worthy of notice and consideration. When the crop is in vigorous growth, the plants should be thinned so that those remaining may have a space between them equal to their own diameter, and no more. This will prevent overgrowth, and cause the roots to be solid and well shaped.

Western Immigration.—The unexampled increase in the current of emigration westward of the present season, is remarkable. A fair idea of the extent of the movement, may be gathered from a statement of the sales of land by land grant railroads during the first four months of 1878, as compared with those for the corresponding period of 1877. Last year, the sales from January 1st to May 1st, were 26,601 acres; this year, 967,151 acres, in value nearly \$4,000,000. The increase is 32½ times. In this are not included the vast number of homesteads or pre-emption entries along the routes of these roads, which far surpass in number the settlements upon purchased lands. The rush westward consists in great part of mechanics and laboring men who hope to improve their circumstances by working for themselves instead of for others, and of business men who have succumbed to the pressure of too many men in trade. It is not to be feared that the great increase in production will injuriously affect the interests of farmers elsewhere. Every ear-load of produce grown in the West, or elsewhere in fact, gives work for many hands in transporting and manufacturing; it creates also a market for tools, clothes, stock, and other necessities, which in the aggregate makes employment for thousands. Thus general industry is excited, and the increased product is needed to feed those whose labor is required to dispose of it, at home, as well as for enlarging foreign markets.

More Wheat to the Acre.

That the ten, fifteen, and even thirty bushel wheat-crops are not the largest that any good wheat-soil is capable of producing, is a fact patent to every intelligent farmer; yet thousands go on raising these comparatively unprofitable crops, even though the means is at hand for largely increasing them. It is really quite within the possibilities of any farm suitable for raising wheat at all, to grow an average crop of over 30 bushels per acre; and 40, 50, and even 60 bushels may reasonably be expected under proper culture. Such crops are rather the rule than the exception on good English wheat farms, but are quite rare in this country.

The cost of fitting the soil, of seed, sowing, interest on the land, and the number and value of the stock and implements required are the same for a small as for a large crop; and the cost of harvesting is but little more in the latter case. So that

the difference between a 10 and a 30 bushel crop is nearly all profit. But how shall this extra 20 bushels profit per acre be gained? By the use of sufficient manure, to make the increase. The fact that extra manuring makes an addition to the crop which is nearly all profit, is a fact seldom realized by farmers; but such is the case, as most will admit, after considering the above statements. The spreading of six cords of stable manure on two acres of land may not produce a crop which will more than pay the expenses of its production; put the same manure on one acre, and the chances are that just as much wheat will be harvested, and at little more than half the cost. For the generality of farmers it would be a safe rule to use what stable manure they have on half the area it is now applied to. But to get the largest return from the farm, and to utilize every acre, is a laudable ambition of every good farmer. To do this, he cannot depend—as many do—on the natural fertility of the soil, or on stable manure; but he must resort to artificial fertilizers, which can now be bought with safety of reliable dealers, with reasonable certainty of getting what is bargained for. This piecing out of the farm and soil resources by use of honest manufactured manures is working a revolution in American agriculture; and in no department may it be better considered than in grain farming. In the use of these fertilizers, however, the same rule applies as with stable manure: that while a certain small amount per acre may only produce a crop large enough to pay expenses, half as much more may cause a handsome profit. We would not advise, however, that a novice in the use of fertilizers should go to large expense at first, but recommend small beginnings, though boldness may perhaps lead to a surprising success. When practicable, the farmer may make a good wheat manure of 300 lbs. of superphosphate of lime containing ammonia (i. e., made of fresh bone), or the same amount of fine bone composted for three months; this for use on an acre. Apply also—not mixing the two—all the unleached wood-ashes that can be got. An occasional liberal dressing of lime will improve wheat land which is already rich in organic matter.

But to grow wheat at a profit, the question of fertility is not the only point to be considered. In all the older States, wheat-growing, to be successful, requires the best kind of farming. The best seed must be selected: for with poor seed, the best culture practised can not produce a good crop. The variety chosen should be both prolific and hardy. The soil, as a rule, should be a fine clay loam, well drained, and contain a fair proportion of thoroughly decomposed organic matter. The plowing should be only 6 or 7 inches deep, the soil thoroughly pulverized and compact, with all the clods on the surface; the seed drilled in early, and rolled, and the rows far enough apart to admit of several cultivations. Then, with a good season, and comparative freedom from insects and disease, and the use of proper implements in harvesting, a large and profitable crop may be expected. In the virgin soils of the extreme West, remunerative crops may perhaps still be raised by the old careless methods, but the time is close at hand when all these conditions will apply there as well as in the older sections of the country.

Beet Sugar Company of Maine.—An official circular from this Company at Portland, is evidence that something practical in the way of making beet sugar in that State is intended. The circular contains directions for cultivation, and a statement that more than 2,000 farmers have interested themselves in this enterprise. The production of a sugar-beet from which sugar can be manufactured at a profit, is still a matter of experiment. The soil and climate of any locality are important points, and success cannot be assured until these are known to be favorable. The business is one in which success depends upon the exercise of small economies, as well as skillful management—for example, the utilization of the refuse pulp is a matter of no little importance. The profit in this last item alone, has often sufficed in European factories to turn the balance towards success, and neglect of it, has resulted in a failure of the whole business.

Laundry Machinery.

At first thought, one might think that very few readers of the *American Agriculturist* would be interested in steam laundry machinery; but when it is known that this journal is taken generally at all insti-

Fig. 1.—BALDWIN'S STEAM MANGLE.

tutions, such as asylums, State institutions, boarding schools, colleges, summer hotels, etc., having farms attached to supply the large number of people at such places with fresh garden and stable products—when this fact is understood, the reason is clear. The managers of these establishments find the *American Agriculturist* of great value in their farm operations, and also in their large households. As of interest to this large class of our readers, we present an illustration of "Baldwin's Steam Mangle," (fig. 1), made by the Standard Laundry Machinery Company of Boston and New York. The advantages of such an apparatus are claimed to be, the saving of labor and fuel, and less damage to the clothing smoothed. Only those who know the

Fig. 2.—STANDARD POWER WASHER.

heat and hard work of ironing for a small family, can fully appreciate the relief that a machine like this affords when the family numbers hundreds. The same concern also manufacture steam washing-machines. Fig. 2 represents the "Standard Power Washer," used exclusively for collars and cuffs. This house also makes superior hand-mangles and washing-machines for family use.

Cow Milkers.

In the June *American Agriculturist* was published an article describing a cow milker, which operated by means of silver tubes inserted into the cow's teats, and connected with tubes of rubber. There are several milkers now offered with considerable rivalry between dealers as to the claimed merits of their respective implements, and a consequent large number of inquiries from our readers concerning them. We have so canvassed the matter as to come to the following conclusion: Several have found that, although the apparatus worked well at first, after a while it made the cow's teats sore; others find that the yield is lessened; others still use it, and have for some time, with uniformly good results, and are much pleased with the apparatus. We have seen some cows stand quietly under its working, while others were restless and dissatisfied. One of the editors of the *American Agriculturist* has had a milker in use for two months, and says of it:—"The supply of milk is steady, and there is no difference in the quantity drawn by the tubes or by hand. During the past hot weather, when the yield might be expected to

fall off, it has kept up to the usual amount. There is no perceptible effect upon the teats in any way; certainly no injury has as yet occurred. But we find it necessary to give some caution as regards the use of the tubes. The membrane lining the teats is delicate, and if the tubes are not inserted with special care, the cow resists, showing that it is painful to her. By using care, however, and giving the tube a screwing motion, there seems to be no difficulty, and the cow shows no objection." On the whole, perhaps the safest conclusion for farmers generally will be, that when the milking is done by a careful, intelligent man, without prejudice against new implements, the cow milker will be a success. But when the milking is intrusted to ordinary workmen, there are strong doubts of its being of any value as a labor-saving apparatus, even if it be not a positive injury to the cows. In short, we are not prepared to recommend any of the milking appliances so far introduced, for general use by farmers. As to the three milkers recently placed before our readers in the advertising columns of the *American Agriculturist*, we see no special merit in any one not possessed by the others, as they are essentially the same in principle. If there is any difference, it may be that the tubes described in the June number have a smoother surface and large holes, and so reduce the friction to a minimum, while still allowing a ready flow of milk and easy cleansing.

Some English Notes.

A Great Estate.—To illustrate the grand scale on which some of the English estates are laid out, I may mention that the Chatsworth Estate of the Duke of Devonshire contains 2,000 acres, which he retains for his private park and flower garden, besides thousands more that are rented for farming. His park is bounded on all sides by hills, which cut it off from the rest of the world, and no other house than his own can be seen from the windows of his grand mansion. His flower garden alone comprises 102 acres, wherein sixty laborers are constantly employed to keep it in order. The remainder of the 2,000 acres is all in grass and woodland, and stocked with deer. A forester has charge of this part of the estate, and the understanding with him is, that he shall have at his disposal all the produce from the deer—venison, pelts, horns, etc.—on condition that he shall keep at least 2,000 head constantly in the herd. The head gardener assured me that the forester's berth is a desirable one.

The Prices of Farm Produce and meat in most parts of England seem to be substantially the same as in America. In many cases, I found them less in the cities than in country towns. The farmers here labor under a great disadvantage, inasmuch as they seldom own their land, all the farm land in England being owned by only a few thousand proprietors; and they are obliged to pay the land-owner an annual rent of from £2 to £10 (\$10 to \$50) per acre, including roads, hedges, and other unproductive parts, and the payment of taxes. The Duke of Devonshire has one of the largest estates in England, and rents the whole, excepting 2,000 acres contained in his Chatsworth Park, to one person, at £2 (\$10) per acre, plus the taxes, the Duke being responsible for merely his income tax. Does the American farmer sufficiently appreciate his freedom from this burden?

The Seasons in England are very different from our own. For instance, at this time (June 10th), the farmers in Kent are in the midst of their hay harvest, and yet the wheat is no further advanced than that in New York on May 10, and they are now putting in their turnips. Potatoes are now in blossom, but new potatoes, from other sections, have been in the market for weeks.

English Farmers complain of an unusually wet season, and we can not doubt the justice of the complaint, for during the two weeks that we recently spent there, but one day passed without more or less rain. Many of the crops have been injured thereby, particularly the wheat, which is yellow and spindling, and the demand upon Amer-

ica for breadstuffs will no doubt be materially increased in consequence.

Hops.—Every considerable town in England has its Hop Exchange. Kent, which we have just passed through, abounds in hop-fields, admirably cultivated, which, at this season of the year, present a very attractive appearance. The poles are arranged in many different ways—some vertical, in single or double rows; some are leaned at an angle of 45°, while others are furnished with strings, extending to the ground, or from pole to pole.

Horse-beans are now (June 9th) in bloom in England, where they are raised very largely, and their peculiar blossoms, resembling those of the pea, but larger, and lined with black, have frequently attracted my attention. They are raised in rows, quite close together, and cultivated by hand. The beans are sometimes ground, sometimes fed whole, mixed with oats, and used as feed for horses. The production per acre is very large, and as they are considered very nutritious, it is to be regretted that they will not succeed in America.

The Red, or Pink, Horse-chestnut, is common throughout England, forming an attractive shade tree, and when in blossom there is none more ornamental. The horse-chestnut, probably owing to the less intense heat, attains here a greater size and better proportions than with us.

Dover, Eng., June, 1878.

G. W. W. H.

American Agriculturist Experimental Farm.

The Rain-gauge in connection with the Lysimeter—described last month—showed a rainfall of 1½ inch on June 21st. This indicates that there fell on the surface of the Lysimeter about 1½ cubic foot of water (or exactly 1.814 cubic feet), and upon an acre 3,000 times as much (the Lysimeter surface is 1/3000 of an acre), or 5,442 cubic feet, equal to about 170 tons of water upon a single acre; yet the Lysimeter showed no trace of water running through the soil. All of the water of this rainfall was held in the soil, the greater portion of it to be absorbed by the roots, and subsequently to pass off through the foliage of the grass growing on the land. This simple fact, recorded by the Rain-gauge and Lysimeter, tells more than volumes of reasoning about the immense importance of water to crops, and when the rains do not supply sufficient moisture, what material benefit irrigation may be to a field. We regret that this apparatus was not in position early enough to show how much water was used by the grass during the entire growing season.

The Amber Cane Sorghum is a failure this year on our Experimental Farm, owing, perhaps, to the extremely wet spring, and the natural moisture of the land. This crop needs a light, dry soil, and, for its best development, a warm spring. The failure, however, is just as instructive as a successful crop would have been, as it warns farmers not to attempt to grow this crop on heavy soils without further light, thus saving them from possible loss; and this is as much a part of the plan of the farm as to show what can be raised at a profit—"a penny saved is a penny earned." Another season's trial, however, may make a different showing, and result in changing our views of the value of the crop for such locations, as it is reported very successful in the West, on light soils, under proper treatment, and other conditions. The five acres occupied by the Amber Cane has been worked up with a Randall wheel-harrow—saving a small patch where the cane made a good growth—and fodder-corn and turnips planted, thus utilizing the fertilizer and the land, and only losing the seed and the labor expended on the Sorghum.

Hungarian grass has been planted on three acres of sod land, with different fertilizers, to test the value of the crop for our section, and its adaptability to the soil. This is now well established as a valuable fodder-crop for both cows and horses. It needs a light soil, is a very rapid grower, yields three to four tons per acre under good culture, and may be

planted any time from the 1st of July to the 10th of August. It is a good second crop, and does well on sod plowed after haying. A quick acting artificial fertilizer is the best manure for the crop—say 200 lbs. of superphosphate, 150 lbs. of nitrate of soda, and 100 lbs. of high-grade muriate of potash, per acre. In our trials of this year, we hope to learn something more definite in regard to the plant-food requirements of the crop. It should be cut while still quite green, as, if left until ripe, it has some qualities injurious to animals. When the hay crop is short, this will be found an excellent substitute to fill out the lacking supply of fodder. "Hungarian grass cut green and well cured, is used by some good Vermont dairymen as a special food for butter cows, and they claim that it has the effect of giving butter the true summer yellow. It is suggested that since Hungarian so cured remains bright and green all winter, and because one of the elementary colors which goes to make green is yellow, that it is this greenness of the fodder which imparts the yellow color to the butter."

Science Applied to Farming.—XLIV.

Formulas For Fertilizers.

Formulas for fertilizers for particular crops are based upon the principle of successful agriculture, that the soil must be supplied with the plant-food that the plants take from it, or it can not produce crops. They differ in respect to the proportions of the several ingredients which they assume, (1) that the plant takes from the atmosphere, (2) that the soil can contribute from its own stores or from what it gathers from the air, and (3) that must consequently be supplied in the fertilizer. For instance, a crop of fifty bushels of corn with the stalks would take from the soil on the average:

Nitrogen.....	75 lbs.	Magnesia.....	23 lbs.
Phosphoric Acid.....	51 "	Lime.....	27 "
Potash.....	72 "	Sulphuric Acid.....	8 "

We may make our mixture so as to furnish all these six ingredients; or we may assume as the result of general experience, that nitrogen, phosphoric acid, and potash, are the only ones the soil will fail to furnish in plenty; or that, if lime and sulphuric acid are needed in addition, there will be enough in the superphosphates and other materials used, to supply them. This plan of furnishing in the fertilizer the quantities of nitrogen, phosphoric acid, and potash, found in the crop, has been adopted by various experimenters, and makers and users of fertilizers in this country and in Europe, and notably by Prof. Stockbridge, of the Massachusetts Agricultural College. Aside from the effects of climate, physical character of soil, tillage, and so on, which affect very materially the feeding of plants and the action of fertilizers, there are two

Chief Difficulties with Formulas

for special crops. The first is that they do not take into account the materials that the soil can furnish: they can not do this because soils vary in their supplies of plant-food. Some lack one ingredient, others another, and the fertilizer which covers all cases must include materials that will be superfluous for some soils. The other applies to formulas based solely on the composition of the crop: it is that they ignore what may be called

The Feeding Capacities of Different Crops.

Plants vary widely in their power to avail themselves of the materials contained in the air and soil. Leguminous crops, like clover, will, somehow or other, gather a good supply of nitrogen where cereals, such as wheat, barley, rye, and oats, would half starve for lack of it, and this in the face of the fact that leguminous plants contain a great deal of nitrogen, and cereals relatively little. Hence a heavy nitrogenous manuring may pay well for wheat and be in large part lost on clover.

This fact is most strikingly shown in the classic experiments of Messrs. Lawes and Gilbert, in England, by bringing out the details of which, in his book on Manures, just announced by the *Orange Judd Company*, Mr. Harris is rendering to the farmers of this country most excellent service. In their experiments, wheat, which has for thirty

years received mineral manures alone, has averaged 16½ bushels per acre yearly, against 14 bushels unmanured. The addition of sulphate ammonia, with repeated cropping of the same land, brought the average up to 36 bushels per acre. The leguminous crops have told just the opposite story. Though they contain a good deal more nitrogen than wheat, they respond but slightly to nitrogen, and are greatly aided by mineral manures. In an experiment on the mixed herbage of grass land, continued through twenty years, mineral manures without potash brought up the total crop 47 per cent, and the nitrogen in the crop 38 lbs. per acre annually above the unmanured. And when potash was added to the mineral manures, the crop was 67 per cent larger, and contained 56 lbs. more nitrogen per acre than the unmanured. Such facts explain why it is such good farm practice to use mineral fertilizers, as plaster, bone, ashes, and potash salts, for mixed grasses and clover; and nitrogenous materials, like guano, sulphate of ammonia, and nitrate of soda, for grain crops. They help us to understand why clover is such an excellent preparatory crop for wheat, and so economical generally for plowing under to bring up poor soils. It gathers and stores plant-food, particularly nitrogen, and thus is itself a fertilizer.

The "Stockbridge Manures."

In the Annual Report of the Mass. Agricultural College for 1876, Prof. Stockbridge gives formulas for fertilizers based upon the composition of crops, and accounts of a long and laborious series of experiments made with them, on the College farm, in which the crops averaged better than the fertilizers were calculated to bring, with many other valuable details. These formulas provided for all of the nitrogen, phosphoric acid, and potash, contained in the crop. The precludes to the formulas read: "To produce 25 bushels of wheat and the natural proportion of straw per acre more than the natural yield," and so on for corn, clover, and other crops.

In such fertilizers the potash and phosphoric acid not used the first season, will be held by the soil until they are taken up by the crops that follow. But more or less of the nitrogen will probably be leached away in drainage waters, enter into inert combinations in the soil, or escape and be dissipated in the air. Nitrogen is the costliest ingredient of fertilizers. In the better articles in the markets, farmers are paying from 4 to 8 ets. per lb. for potash, from 5 to 15 ets. per lb. for phosphoric acid, and from 17 to 27 ets. per lb. for nitrogen.

Such crops as wheat, barley, rye, and oats, bring the largest returns for nitrogenous manures. But the results of experiments and of successful farm experience with fertilizers, which, like guano, phosphates and bone, contain less nitrogen, unite in making it a question whether it will pay to apply the full amount of nitrogen found in such crops as wheat, barley, rye, or oats, or even corn.

The case against the nitrogen in the clover fertilizer is still worse. When we consider how often clover thrives with mineral fertilizers alone; how, on a mineral diet, it will gather nitrogen from soil and air and store it for future use; how the great advantage of such crops to the farmer, is that, instead of consuming nitrogen which he must buy at great cost, they gather it for him for nothing; the plan of supplying so much nitrogen to clover seems poor economy. Experiments might be cited, which, like the above, illustrate the principle that the composition of a given crop is far from being a correct measure of the fertilizing materials which will most economically help its growth. At the same time it is fair that

The Other Side of the Question

should be given. And I can do this no better than in the words of Prof. Stockbridge, spoken before the Conn. State Board of Agriculture, Dec., 1876:

"I agree that some plants can gather nitrogen from natural sources, and we need not apply it. All probably gather some, and some classes of plants more than others. I hope that Prof. Atwater, myself, or somebody else, will find the law there by-and-by; when it will be I don't know. I have had sixteen plats on trial this year, looking for that very thing. I have not found it yet; but I shall put the sixteen plats and more too after it next year, and I shall keep on until I think I have found it. There is

no mistake about the fact that clover, beans, and the legumes generally, are great gatherers of nitrogen. It is probable that wheat gathers some. And yet, in our present condition, from our present standpoint, I do not dare to risk it. I do not dare to send out a fertilizer and say that it will do so-and-so, unless I put all the things in. I agree with Prof. Atwater that there is a little loss here. I have put nitrogen for some crops that I know I need not have paid for. There is a little loss of potash, for I have put in potash for some crops that I need not have paid for. That is exactly so. But here is the point. I find it would be utterly impossible for practical farmers, taking them as we find them, going on with their ordinary system of farming, to ascertain the fact whether they need

learned to rate at their true value, has already modified some of his formulas, a fact which accords with their lower price, and I have no doubt he will keep doing so as rapidly as he thinks safe.

W. O. ATWATER.

Wesleyan University, Middletown, Conn.

A House, or a Parsonage, Costing \$3,700.

BY S. B. REED, ARCHITECT, CORONA, NEW YORK.

This plan is intended for a compact and economical residence or a parsonage, containing thirteen rooms, ample halls, eleven closets, large cellar, heater, range, cold and hot water, with all the necessary modern improvements suitable for the uses of a good-sized family.... **Exterior.**—The general outline is nearly square, 26 x 30 feet, which, while the most simple and economical form of construction, affords the best opportunity for a desirable distribution of rooms. The porch, bay-window, and lobby, provide projections that break up and relieve the monotony usually observed in square buildings.... **Interior.**—The interior arrangements partake very much of the character of a "double house," particularly in the upper stories.... **Cellar.**—The cellar extends under the whole house, and contains the heater and bins for coal, etc. The heater ("portable") is arranged to provide warm air to each room in the two principal stories, except the kitchen....

First Story, (fig. 2.)—The entrance, or reception hall, is large, and contains the principal stairway of the house, so arranged that the quarter-circle is about midway of their height, placing the niche down where it adds greatly to the good appearance of the hall. The principal rooms, parlor and dining-room, where it is usual for the family to congregate, are spacious and accessible. Each has a large bay-window, adding to its area, and supplying a pleasant outlook. The dining-room has a large closet for china, etc., occupying the space under the main stairs. The kitchen adjoins the dining-room and the rear entrance, or lobby, and has direct communication with the cellar-stairway through a door. It is provided with a range, boiler, sink, pump, and wash-tubs, complete. The copper boiler is placed above the range in an arched recess in the chimney-breast, and is inclosed with an iron door. The lobby, or rear entrance, is arranged to connect by doors with the dining-room, kitchen, and private stairway leading to the second floor....

Second Story, (fig. 3.)—The stairs "land" nearly in the center of the second story. Very little space is required for the second-story hall, leaving almost this entire floor to be laid off in rooms. These rooms may all be used as chambers, or any one of them may be used as a study. Doubtless the room directly above the front entrance would be best adapted for that purpose. The door leading to this room should have ground-glass upper panels to supply light to the hall of this story.... **Attic, (fig. 4.)**—The attic story is reached by the stairway, shown at the front end of the second-story hall, which has a door at the foot to shut off all communication at pleasure. This story is divided into four rooms, four closets, and hall. The hall is lighted through an opening, or skylight, in the roof, which also serves as a ventilator. The school, or play-room, is put in this part of the house, where noise is less likely to disturb the older members of the household. [To fit this house for country places or villages where there is not a reservoir supply of water, a large Tank should be provided on the 3d floor, to receive water from the roof, with a force-pump to fill it in dry seasons. This might occupy a part of the largest closet at the right of the chimney.—ED.] A work-shop, having ample space for a work-bench, wood-lathe, and other tools, is provided for in our plan on the third floor.... The estimate appended indicates the general character of the work

to be good and substantial. Provision is made for brick foundations, a regular timber frame, double siding, slate and tin roofs, outside blinds, panelled doors, simple and appropriate trimmings throughout, with marble mantles and stucco cornices in the principal rooms of the first story. The figures set down for the cost of windows, bays, porch, lobby,

potash or not. Prof. Atwater will find it out; perhaps I might find it out, but taking farmers generally, I think there would be a failure. I say that I think I know that with nitrogen, potash, and phosphoric acid, mixed in a certain way, farmers will get their crops; I do not know but they would get their crops if I left out a little potash; I do not know but they would if I left out some other thing; but as I say, I do not dare to risk it. Give me time enough, and perhaps I will run these little threads out, and find out how much nitrogen I should leave out of the corn-fertilizer, or out of the wheat fertilizer, or out of the clover fertilizer, but you must give me time. Until I learn that, I say, 'I know nitrogen, potash, and

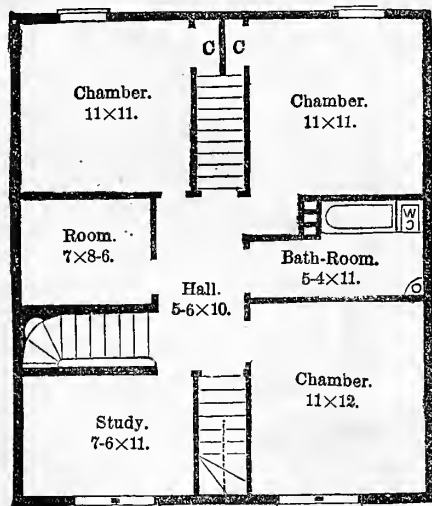

Fig. 2.—PLAN OF SECOND FLOOR.

phosphoric acid will do such-and-such things.' I do not know but I might take out a little. Until I do know, I do not dare to change my formula as a rule of general application."

I understand Prof. Stockbridge, whose position has, I believe, been misinterpreted, and whose labors the farmers of the country have not yet

Fig. 3.—PLAN OF FIRST FLOOR.

and doors, include both materials and labor. The \$300 for carpenters' labor is for the balance.

Estimate for house with Mansard roof:

75 yards excavation, at 20c. per yard.....	\$15.00
13,000 brick, furnished and laid, at \$12 per M.....	156.00
48 ft. stone sills, steps, and coping, at 40c. per ft....	19.20
1,000 yards three-coat plastering, at 25c. per yard....	250.00
550 ft. stucco cornices, with centers.....	75.00
4,181 ft. of timber, at \$15 per M.....	62.71
2 sills, 4x8 in. 26 ft. long.....	22.00
2 sills, 4x8 in. 30 ft. long.....	5.00
6 posts, 4x7 in. 23 ft. long.....	120.75
1 girder, 4x8 in. 38 ft. long.....	15.00
4 ties, 4x6 in. 26 ft. long.....	114.30
4 ties, 4x8 in. 30 ft. long.....	67.20
4 hips, 3x7 in. 16 ft. long.....	100.00
100 joists, 3x4 in. 13 ft. at 2c. each.....	
500 wall-strips, 2x4 in. 13 ft. at 11c. each.....	
483 sheathing for sills and roofs, at 25c. each.....	
300 lbs. tarred felt, at 5c. per lb.....	
381 novelty siding, 6-inch, at 30c. each.....	
112 ft. main cornice, at 90c. per ft.....	
10 squares of slate, at 10c. per ft.....	

Fig. 4.—PLAN OF ATTIC.

12½ squares of tin, at 10c. per ft.....	125.00
8 cellar windows, complete, at \$8 each.....	64.00
12 plain windows, complete, at \$12 each.....	144.00
8 dormer windows, complete, at \$20 each.....	160.00
2 bay-windows, complete, at \$60 each.....	120.00
1 porch, complete, \$75; 1 lobby, complete, \$50.....	125.00
390 tongued and grooved flooring, comp'l, at 25c. ea.....	109.20
46 doors, complete, at \$10 each.....	460.00
11 close s, complete, at \$6 each.....	66.00
2 marble mantels, complete, at \$25 each.....	50.00
1 heater, complete.....	200.00
Gas-pipes, \$33.71; Plumbing, \$188.98; Carting, \$75.....	299.64
Plumbing, including range, etc.....	300.00
Extras, for hardware, etc.....	75.00
Carpenters' labor, not included above.....	300.00
Total amount.....	\$3,700.00

Shepherd Dogs.

The Scotch Colley dogs are remarkable for great intelligence; an instinct which seems sometimes to surpass reason; wonderful endurance, and activity. Without these dogs, sheep-keeping in many districts, useful for no other branch of agriculture,

trained to manage with gentleness any kind of live-stock. He is domestic in his habits. While kind and affectionate to his owner, and his herds, he is watchful and suspicious of strangers and strange animals. His good disposition gives him great influence over his charge, and causes them to have confidence in him. When a flock is afraid of the shepherd's dog, it shows wrong management

SCOTCH COLLEY DOGS.

would be impossible. The home of this breed is the Scotch highlands, a locality of rocks and hills, interspersed with grassy valleys; elevated table lands bearing scanty herbage, and "moors," or level or slightly undulating tracts covered with gorse, heather, low bushes, boggy places, and scattered rocks. Upon these hills sheep are kept in large flocks, exposed from day to day to all the vicissitudes of storms, mists, rains, and snows, with no other shelter than is afforded by the lee-side of abrupt precipices, overhanging rocks, stone walls, or in rough sheds of poles and heather. Without his dogs the shepherd would be helpless to manage his flock in this rough country. In countries where arable land bears a very high price, only such land as can not be plowed is given up to sheep pastures; and here the dog is invaluable: and not only here, for he is made useful upon the more civilized hill-sides of the Scotch low-lands; upon the grassy downs of England, the rich farms where sheep-keeping is only incident to high culture; and upon our own Western plains. Everywhere, where sheep are kept, a sheep dog of some kind is found useful; and of all the different varieties the Scotch Colley is considered the most valuable. He possesses a rare instinct for his work, which comes as a second nature to him. He often knows the ways of sheep better than his master, and understands the signals of the shepherd when far out of hearing, with great precision. Cases have been known in which the dog has discovered the absence of some laggards of the flock which his master had not missed, and has returned to the pasture for them unbidden. He can range his flock upon one side of a road, when meeting other sheep, and thus keep them from intermingling with the strangers. He will discover by his acute sense of smell sheep that have been overwhelmed in snow-drifts, and will conduct the shepherd to the place. If no help is available, he has been known to dig into the drift and release imprisoned sheep, and to warm chilled lambs by huddling close to them. He is valiant in their defence, and will give battle to a wolf without hesitation. No vagrant dog will be permitted to approach a flock of which he has charge. He will bring back stragglers when upon the march, and will return to find the sore-footed ones that have lingered by the way. For a farm dog he is of special value, as he can easily be

on the part of the shepherd, and that the dog has been badly trained. The Scotch Colley has long and woolly hair; a bright mild eye; a sharp nose; an intelligent aspect; a long bushy tail, curling upwards, with the end clear of the ground; and in color is usually black and tan, variegated with a little white. The illustration pictures three dogs of this breed, owned by Francis Morris, of Philadelphia. Not the least wonderful or useful characteristic of the dog is his tenacious memory, by which he is able to remember all the turning points in a journey of hundreds of miles, and to recognize at

THE FOX-TERRIER.

sight every member of the flock to which he has become attached. With all his good qualifications, however, he sometimes lapses from virtue; and no other dog is so destructive in the fold as a sheep dog become demoralized by bad companions. A traitor is the worst of enemies.

A Useful Farm Dog.

The fox-terrier is a great favorite in Great Britain, and is getting quite well known in this country as a useful dog on the farm. For unearthing foxes he is as able as a ferret after rabbits; and in killing all sorts of vermin—rabbits, woodchucks, skunks, rats, mice, squirrels, etc.—he has few equals; and next to a shepherd dog, there is none the farmer stands more in need of than one to destroy the vermin which prey upon his crops, trees and shrubbery. The fox-terrier is plucky, and brave as dog can be, facing danger and death like a true soldier. He is small, neat, and comely easy to handle, and quick to obey. The "Tartar" strain, it is said, should be avoided, as being an objectionable mixture with bull-terrier blood. A writer in an English paper, the "Country," thus describes what he claims to be the true type of the fox-terrier: "Head level, and well filled up under the eyes; long and powerful jaw, with just a suspicion of fleg, rather square, decidedly not a fast taper; ears small and drooping close—this is a *sine qua non*; eyes small and expressive; deep and rather narrow chest; shoulders well set back, with elbows working as straight to side as the cocks on a double barrel; legs as straight as arrows; feet round, toes slightly arched, and not the least splayed; short body, well ribbed up; can not have too much bone or muscle; must be as cobby as possible, and should be very near a breeder's definition of what a Shorthorn should be—a brick with the corners knocked off. He should not be more than seventeen pound weight, which is imperative; and his heart should be in the right place. He should stand low, and his coat, though close, should be dense and hard. The fox-terrier, as I have found him, is pre-eminently an intelligent dog, 'at all times to our will conformable, ever in fear to kindle our dislike.'"

Rich Soil for Roots.—A fair shaped mangel or turnip cannot be grown upon poor soil, even though freshly manured. To grow a well-shaped, dense root, without lateral fibres of great thickness, spreading like the outstretched fingers of a hand, the plant-food must be equally and thoroughly mixed with the soil, so that each fibre can reach it without travelling far. Then the nutriment is

brought from all quarters to the bulb, and its growth is regular, the fine root fibres being numerous, evenly distributed, while the tap-root descends straight downward. This condition of the soil cannot be procured by the application of fresh manure, but may be by the previous application of

that which is fine, and well decomposed. However, by plentiful fertilizing with the prepared artificial manures, and by thoroughly mixing these with the soil by harrowing, a very fair crop of good roots may be grown even upon comparatively poor land. The fine condition and ready solubility of the fertilizers have an immediate effect upon the soil, and enable the plants to procure the nourishment most readily assimilated as fast as the crop requires it.

Among the Farmers.—No. 31.

BY ONE OF THEM.

Old Wethersfield

Was represented by one of the three grape-vines on the seal and coat of arms of Connecticut, encircling which, the motto "*Qui Transtulit Sustinet*," indicates the abiding faith which gave strength to the pilgrim band who settled Hartford, Windsor, and Wethersfield, planting a "Vineyard of the Lord" in the heart of the wilderness, amid privations and trials, and dangers which can not now be paralleled. The placid Connecticut then as now brought fertility to the meadows in the spring freshets; shad and salmon to the very doors of the settlers, together with the means of communicating with the outside world much more conveniently than by hewing their own way through a primeval forest 100 miles with their ox-teams and axes. Wethersfield was always a quiet restful place to me. I associate it with after-supper drives (we say after dinner now-a-days), when the great elms cast no shadows on the street or roads, and when onion-weeding was over for the day, and the girls had unbent their calloused knees, and were tripping about, enjoying the cool of the evening after their day's work in the field. The slender-spined church—"built by the women out of onions," the legend runs—is unchanged. The broad street, still elm embowered, changed but little, and not a few of the old houses are still unaltered; but change is rife even in Wethersfield. Steam-cars and whistles break the silence; horse railway cars rumble at certain hours. Even the seed-business, which for years has spread a sort of beneficent mantle over all the land, near the village, giving in a very quiet way employment to many hands—even this business now obtrudes itself upon the stranger's attention as the great seed warehouse of Wm. Megget, with its lettered roof, looms up the most conspicuous building in the village. One is forced to think of the great yellow and *fruity* labels of the "Wethersfield Seed Gardens," which one meets with in every country store almost from Maine to Georgia, or even, very likely, to far-away Oregon.

Onion Seed.

They raise onions still in Wethersfield, but they export no more—the Connecticut River sloops leave no longer their odorous wakes as they plow the placid Sound. The redolent esculent is raised strictly for home consumption, and for seed, and last year I believe they had actually to import bulbs, as the home supply was insufficient for planting. Immense quantities of seed are raised, and the crop is a beautiful one in all stages—early in the ground, soon giving the peculiar tender bluish green to the fields, requiring clean culture, and changing in appearance greatly as the season advances, and the flower stems push up, and head and blossom. It is off the ground in time for other use of the land, and the seed, when harvested, dried, cleaned, and ready for market, is worth, in different years, from 15 cts. to \$1 a pound. So it pays well some years, and sometimes the seed-growers net a loss.—My visit was particularly to the

Farm of S. M. & D. Wells,

who are among the best farmers in the State, are widely and favorably known as Ayrshire breeders, and raise seeds by contract or for the general market. They were large milk producers and sellers a few years ago, but now look for their profits more in the breeding of fine Ayrshire cattle than in the milk business, which was a good deal damaged by the skim-milk dealers, though to the consumers' advantage. There have been a number of "creameries" or

butter factories started within a few miles of Hartford—two at least—the one at Farmington being the most famous. They sell their skimmed-milk, which during most of the year is quite sweet, to dealers who peddle it from house to house at 3 cts. a quart. The people found that this sweet skimmed-milk was quite as good as the watered milk of most milkmen, and thus the price of milk fell off greatly, and the demand for pure Ayrshire milk, at a fair price, fell off too, so that it was no longer an excitement and a pleasure to produce and market the article. In fact, men ought to be well paid for turning night into day and day into night, as milkmen have to, in order to supply customers with fresh milk for their breakfast. The Wellses work with their men, and I think were really glad of the opportunity to give up this most laborious, though frequently very profitable, branch of farming.

Their Ayrshire Herd

has long been famous throughout the country. They have been judicious and liberal buyers, and good breeders, their stock giving excellent satisfaction wherever it is distributed. I meet not unfrequently animals in high repute tracing to the "Dolleys," "Floras," and "Mysies" of their herd. They have always been good feeders, and as they have been proprietors of a valuable milk route in Hartford, it has been an object to produce the largest quantity of good milk consistent with health. I say *good* milk, for having this reputation they have usually been able to obtain a higher price for their milk than any one else, and such a reputation is worth maintaining. Some years ago, when making experiments with feed, as to the policy of steaming, etc., the yield of the herd was 9½ quarts in winter, and 11½ in summer, to each cow, counting dry cows and all. This makes the general average nearly 3,800 quarts of milk per cow, which is extraordinary. I think I have never visited a stable where the two objects of keeping cows, namely, making both milk and manure, were more thoroughly well done. The cows always have water before them in the stable, and are fed all they will eat, and though kept at the business of calf and milk producing so steadily, they live to old age, and are always in good condition, but not fat. Stimulants are never employed; but pure air, exercise, variety of food, cleanliness, and regularity, are, in my opinion, the reasons for their success.

Home-made Things.

Observing the plain and substantial character of a particular set of double-harness, I learned that it had been made upon the place; a thorough journeyman having been employed, the very best leather bought for him by the side, and a capital job turned out. The harness cost a little more than one apparently as good could have been bought for, and it will outlast two or three "boughten" sets. Not only is the leather of the very best, but the thread is of the first quality, and the sewing thorough. Spots where wear comes, or which are required to be particularly strong, are reinforced by inserting capping, or backing with extra pieces.

An Old Farm-Wagon

was also pointed out, as showing the value of home-made things—home-made in the right way—that is, by a first-rate mechanic working under the direction of the man who is going both to use and pay for the article. It is not necessary that this sort of work should be done upon the place. A neighboring wheelwright will do better work in his own shop than on the farm, but if a man of a little experience and common sense cuts his own timber, seasons it, tests it, selects with the mechanic what is best for spokes, felloes, boulders, reach, etc., he is certain that no dozy or wormy pieces get in, and that with good workmanship, he will have a set of running gear that will stand some "racket," as they say in New England. As to this wagon, it was made some 35 years ago by the father of the Messrs. Wells, and has been in constant use ever since. Not a spoke has failed or loosened; tires, felloes, and the bottom and side-boards of the box, have been worn-out time after time, but the entire running part not exposed to wear with the box-frame, has lasted intact, and is now apparently as

good as ever. I do not doubt many a parallel may be easily found, but our ways of doing things are not changing for the better. We are using the cheap, but gaily painted wagons, spongy, stretchy harness, tricked off with brass, like a brewer's rig, and other showy articles, altogether too much. These things are cheap, and in an emergency are worth the money asked for them, twice over, perhaps, but for steady hard work, and every-day use, are dear at any price.

Onions and Tobacco

on a good clay-loam, well tilled, are very satisfactory crops, even if the price does fluctuate. They require plenty of manure; the soil holds it. They need clean culture, and the soil once free from weeds stays so unless the seed is sown again. Excellent tobacco can be raised with manure enough of the right kind, on the light lands across the river, but the manure does not last in the soil, and being all derived from fields not subjected to the same clean culture required by the tobacco, the entire farm is not benefited as where rotation can be followed, and one field after another be thus enriched and tilled. Potatoes are a prominent crop, and succeed well, and great use is made of

Corn for Fodder.

The variety is Stowell's Evergreen (sweet), sowed in drills 3 feet apart, manured both broadcast and in the drills. A little is put in very early, and fed green from the time it is fit to cut, to frost, and great quantities cured for winter use. The corn is cut up with corn knives, and set up in armfuls, in good sized stooks, securely bound, and well spread out at the butts. Thus it is left until needed, or until it can be hauled in over frozen ground, when it opens out as green, flavorful, and fragrant as well-cured hay. Large crops of mangels and other roots are raised, and a system of cooking the feed of the cattle has been followed for many years. Everything is cut up by horse-power, and mixed in a steaming-box, which is of plank, with a false bottom. The box extends from the cattle-floor into the main floor above, where the fodder is cut, and is large enough to contain two or three days' feed for the whole stock of some 40 milking and breeding cows, and I don't know how many young stock.

Talks on Farm Crops.—No. 18.

By the Author of "*Walks and Talks on the Farm*," "*Harris on the Pig*," etc.

"I have a piece of timber bottom," writes Mr. Cobb, of Kansas, "that I have recently cleared up, and have had it in corn for the last four years. Corn is not very profitable at 20 cts. a bushel."

"I am glad to hear him acknowledge that," said the Deacon. "I have long suspected that the men who figure out such handsome profits on paper from 20-cent corn, are railroad men who have land to sell and freights to carry."

"Hush, Deacon," said I, "there is as much money to be made in raising corn at 20 cents a bushel in many parts of the West, as there is in raising it here at 40 cents a bushel."

"Just about," said the Deacon, sarcastically.

"Well," said the Doctor, "it is no use grumbling at prices. They are beyond our control. All you can do is to raise good crops, and market them to the best advantage. You are not obliged to sell corn at 40 cents a bushel. I paid \$1.50 for a hind-quarter of lamb the other day, and I am sure that farmers could well afford to feed out more corn to their sheep and lambs."

"That is certainly true," said I, "especially if you have the right kind of sheep. As yet, we fail to appreciate the influence which the exportation of meat to England is going to have on our agriculture. We shall feed higher. Our fattening lambs and sheep will have grain every day, summer and winter. It would be a good thing for all concerned, if we could send a million fat sheep to England next year, and two millions the year following. There is nothing in the way, except that we have not got the *fat* sheep. And yet we sell corn for 20 cents a bushel in the West, and 40 here."

"Yes," said the Doctor, "and it is almost impossible, here in the country, to get a good beef-steak. I have to pay 15 cents a pound for the wretchedest kind of beef. Why we do not get Shorthorn bulls and raise better cattle, and feed more corn, is one of the mysteries of human nature."

"Hitherto, Doctor," said I, "we have had no steady market for beef and mutton. Now that this is secured, we shall raise better cattle and sheep, and shall feed higher. But we are wandering."

"This piece of land," continues Mr. Cobb, 'is in fine condition and rich, and will continue to produce a good crop of corn for the next forty years without manure. It ought to produce 30 to 40 bushels of wheat per acre, if I had some good variety. What kind of wheat would be suitable to such a piece of land in Southern Kansas, that has a stiff stem, and not inclined to run to straw?'

The Squire, the Deacon, Charley, and the Doctor, all said the "Clawson."

"But, nevertheless," said I, "it may not be the wheat that Mr. Cobb wants. The fact that it does well here and in Michigan does not prove that it will do well in Southern Kansas. It has stiff straw, and stands up well, but it is such a vigorous grower, that on rich bottom-land and in a southern climate it may run too much to straw. Still, I know of no variety of white wheat that I would sooner risk on such land than the Clawson. I am never very enthusiastic over new varieties of anything. We are inclined to think more of what variety of wheat to sow than about preparation of the soil."

"You should attend to both," said the Doctor, "Make the land in good condition, and then select the variety best suited to your soil and climate."

"That is it, exactly," said I, "but some farmers seem to think they can find a variety that will do well on poor, wet, weedy, half-worked land. Mr. Cobb has the right idea; he has rich land in fine condition, and is wise in looking for the best variety. But I have known a farmer send hundreds of miles for a choice variety of wheat that was advertised in the papers, and sow it on land that was too poor, and wet, and weedy, to grow a crop of rye. We need better varieties of wheat and barley, oats and corn, potatoes and root-crops; but we need still more better cultivation, better manuring, and more prompt and energetic preparation of the land."

"That is all true," said the Doctor, "but farmers are improving their land more rapidly than ever before. Artificial manures are having a decidedly beneficial effect. They put new life into the land; and, better still, new thoughts and new hopes into the farmers and farmers' boys. It is giving tone to our agriculture."

"Perhaps so," said the Deacon, "but what we want is better prices for our produce. It is no use raising crops if we cannot sell them."

"Our crops," said I, "always have sold, and always will sell. Go where you may, you will see the familiar sign, 'Cash for Wheat.' True, the price may not suit us. But those who have wheat to sell are as well off as their brethren who have flour to buy for themselves and their children. Let us be thankful that our crops are as good as they are."

"Would you put in much wheat this fall?" asked Charley. "Probably wheat will be very low."

"I should put in just as much wheat," said the Doctor, "as I could put in well—and no more. We had a great crop of wheat in this section last year, and the wheat now (June 25) on the ground is decidedly better than the average."

"Yes," said the Deacon, "and there was much more land sown to wheat last fall than for many years. It is a rare occurrence to have two such crops of wheat in succession. I think farmers will sow all the wheat they can this fall."

"But," said I, "as they made a very great effort to put in all the wheat they could last year—sowing every acre that could be got ready—I doubt very much whether they will have as much land as usual this fall to sow to wheat. At least three-fourths of all the fall wheat raised in this section is grown after barley and oats. Far less land was sown to barley and oats this spring than usual. Then, again, clover-seed was very cheap, and our wheat is seeded down with clover. It is an unusually good catch. And farmers will not be likely to sow

wheat after wheat, as they are sometimes tempted to do when the clover fails."

"All of which goes to show," said the Doctor, "that the farmers have far less land ready to sow to wheat this fall than was sown last year."

"I should say, with the Doctor, if you have any land that will bring good wheat, do not hesitate to sow it. I have 33 acres in wheat this year, and 30 in barley. As soon as the barley is harvested we shall plow the land and get ready for winter wheat."

"Don't plow it but once," said the Deacon.

"That depends on the land," said I, "and to some extent on the weather. On sandy land, and especially if it is covered with a good crop of weeds, probably you are right. I would plow it once with a jointer plow, and depend on the harrows and cultivators, or gang-plows, to keep down the weeds."

"Would it not be a better plan," asked Charley, "to harrow the stubble with a heavy three-horse harrow? This would start the weed-seeds, and the scattered barley or oats. We did so one year, and I stood on a plank laid across the harrows to drive. I had to get off occasionally to clear the harrows of the stubble and weeds, but it did good in starting the weeds and scattered grain."

"That is so," said I, "and if the new Peruvian Government Agency will sell us nitrate of soda at such prices as we can afford to pay, I should like to dress all my wheat land this fall with 200 lbs. of mineral superphosphate and 150 lbs. of nitrate of soda, per acre; with another 100 lbs. of nitrate of soda sown as a top-dressing in spring, I should expect great wheat. On rich, strong, loamy soils, artificial manures are not so necessary; but it will cost more to get the land ready for the wheat. But I think it is probable that we shall have good wheat on these clay-spots, and good clover afterwards. And so, while it is considerable trouble to get such land into a thoroughly mellow condition, it pays wonderfully well to do it—especially as the land is there and will have to be sown whether we will or no. You want a three-horse plow with a *good point*. And as soon as the land is plowed, *roll it*. If the roller does not break or press down all the clods, harrow, and roll again. Do not leave a clod bigger than a hen's egg on the surface. Harrow and roll until the surface is smooth. This will check evaporation, and the clods that are pressed into the loose, mellow earth will absorb moisture, and become so soft that the cultivator or harrow will make some impression on them. But I would not depend on this alone. Before sowing the wheat I would plow again. If the first plowing was well done, and if the roller and harrows have been used sufficiently, this will turn under four or five inches of moist, mellow soil."

"That is what I object to," said the Deacon. "Why not keep it on top?"

"The plow," said I, "will turn under this mellow soil, and bring up two or three inches of hard, cloddy soil. Roll and harrow, and drill in the wheat deep enough for the seed to reach the moist earth underneath. The drill will pull up some of the clods and leave the surface rough—but this is no objection. I would rather have the clods on top and the mellow soil beneath, rather than the clods underneath and the mellow soil on top. But I am aware that there are two sides to this question. The Deacon and I have a standing quarrel on the point. A good deal depends on circumstances."

The Use of a Roller.—The proper office of the roller is to reduce a cloddy soil to a fine condition, and not to produce a smooth level surface. Rolling may smooth the surface, but it can not make it any more level than it was previously, except to get rid of the small furrows left by the harrow or the drill, which are of service, and should not be obliterated. Rolling is useful when the soil is full of clods, which prevent the proper covering of the seed and the even sprouting of the grain. It is injurious when it compacts the surface and causes it to bake and crust over, by which the soil dries rapidly and receives moisture slowly, or not at all. Then the dew is not absorbed, the atmosphere can not enter to carry moisture into the ground; rains run off from the surface, washing it

and carrying off fertilizers or grass-seed, either altogether or into bunches, by which the plants are caused to come up unevenly. A good use of the roller is upon meadows in spring to smooth the surface for the mower, but at the present season, when fields are about to be prepared for fall grain, farmers may well consider how the roller may be used and misused.

Grades as Milkers.

BY PROF. LEVI STOCKBRIDGE.

A recent writer suggests two very important questions, the facts in relation to which, and the principles controlling the ease, should be well understood by all dairymen and breeders of dairy stock. His query is, Do heifers, from native or scrub mothers by bulls of thoroughbred milking stock, make better milkers than their dams; and if so, why? Why take the qualities of the stock from the sire, rather than the dam? It is an indisputable fact that many native cows are superior milkers and butter-makers, and this quality is transmitted to their daughters in some cases, until a family exists of local celebrity. This characteristic, however, has generally been lost in the course of three or four generations, for want of care in keeping up the regular line, or by the yearly infusion of blood of base or unknown quality. It is quite possible that remarkable milking qualities in an individual native cow might be perpetuated to remote descendants, and even increased, by careful selection of the sire, and in-and-in breeding. But that is the method by which thoroughbreds are produced, and requires skill and intelligence of a high order, and years of observation and labor. With a good native cow as the basis or stock, much anxiety and time may be saved, by an immediate infusion of the fixed blood of a thoroughbred of the desired type, and the result will always answer the first query in the affirmative. The calf will be better than its dam, in some respects, and worse in none. As an accident or sport, it is possible the dam might be a better milker than the dam or breed of the sire, and the calf taking the type of the sire be inferior to her, but the rule taught by experience is the other way. In this case the characteristics of the offspring are determined by the long-known law, that the longer a class of animals is developed in a single line, the greater is their transmitting power, with the more certainty do they impress their qualities on offspring. The blood of the dam having no line of descent, and no accumulated force, is overborne by the thoroughbred sire. Theoretically the progeny of such a connection is more than half-thoroughbred, and should develop more than half of the sire's stock qualities in milk and form. There is but little danger of reversion to original form if this method of breeding be adhered to; but even if there were, it is undoubtedly the cheapest, quickest, and surest way to develop fixed milking qualities from native cows.

[Upon a great majority of the old farms of New England, and the Middle States, cows have been used for milk, and neglecting almost every other quality, bred for milk for many generations. They are well-bred in no other particular, but not a few of them are in this. When such cows are crossed with a bull of any of the established breeds, is it surprising that even a grade Hereford proves a grand milker? That Shorthorn grades, even by sires of families bred rather for beef than for milk, should prove great milkers would be looked for from the fame of their dams and from their own superior form and higher grade as animals. That Ayrshire grades from such a cross should give much milk, and Jersey grades rich milk, we look for as a matter of course.—Ed.]

Weeds.—The worst thing about weeds, is, that the farm of the good cultivator is often stocked with them from the highways and the fence rows or farms of his neighbors. The law in most places provides a remedy and enforces a penalty upon careless or neglectful farmers; but the good farmer is generally a good neighbor, and is greatly disin-

inclined to protect himself by law, and so he suffers without complaint. But there is an unwritten law which exists amongst men, which should impel every one to use his own property so that it may not be made a source of injury to that of others. Every farmer should be made aware of the damage that arises from weeds, the waste of labor that is caused in eradicating them, and the robbery of the soil by their support. If every farmer fully appreciated this, there would soon be a crusade against the whole army of weeds.

A Harrow for All Work.

S. H., Griggsville, Illinois, sends a description of a good harrow. It is made in two parts or wings, each of which consists of four bars connected with

A HANDY HARROW.

three cross-ties, the two outer ones having strips of light bar-iron beneath them and under the bars; and as the bolts pass through these, it gives great strength to the implement, notwithstanding its lightness. Upon each wing there is an adjusting bar, furnished with a number of holes, which operates as a brace to spread the harrow as desired. The teeth may be made to stand upright or to slope backwards, as the builder wishes. By using the sloping teeth, the harrow may be used to clean wheat fields in the spring, or to harrow young corn or potatoes, as is frequently done. A light harrow of this kind, furnished with both upright and sloping teeth, may be made to do varied work, and will be found a very desirable implement.

Slatted Floors for Cow-Stables.

The greatest difficulty experienced in the management of a dairy is to provide an effective method of

Fig. 1.—SECTION OF GRATED FLOORS.

keeping the cows clean. Stalls provided with stanchions, and gutters in the rear to catch the droppings, is probably the best method at present used in dairies; but an improvement upon this may easily be made by using slatted or grated floors. These have long been used in English stables, and have been introduced in this country by at least one enterprising farmer. Mr. E. W. Stewart, of Buffalo, N. Y., has provided his stables with a floor of this kind, and has found it very effective in keeping his cows cleanly, and in saving labor. His method is very similar to that in use by the well known English farmer, Mr. Mechi, who speaks very highly of the system, and considers the cost to be abundantly repaid in the lessened labor and improved condition of the cows. The cost for this improvement, complete in every respect, need not be over \$6 per cow, or but \$120 for 20 cows. The arrangement of the floor of the stable may be as shown at figure 1. The feed passage is at a; the stanchions at b; the grated floor at c; the manure gutter at d; and the drive-way for a wagon or cart to remove the manure at e. The grating is shown

at figure 2, and is made of iron bars 1 1/2-inch wide and three-eighths of an inch thick. The cross-bars are placed with the edges up and down, about one inch or one inch and a half apart, and are riveted to the end bars. The gratings are 12 to 18 inches

Fig. 2.—THE GRATING.

wide, and may be made of such lengths as will answer for one or more cows. They will answer either for stalls or an open floor with stanchions. Rings or eyes are riveted on to the front bars by which the gratings may be hinged by staples to the timber in the solid floor. The front part of the floor is made of plank or concrete, or may be of earth; but there must be a timber bedded in the floor in either of the last cases, to which the gratings are hinged, so that they can be lifted up for the purpose of cleaning out the gutters when necessary. The form of the gratings is shown at figure 2. The rear portion rests upon wooden posts, stone blocks, or angle-iron pillars, as shown at figure 3. The latter is, perhaps, the best arrangement, although square stone blocks bedded in the cement of the gutter are durable and cheap. If the iron posts are used, they should be set in a beam of wood, bedded in the cement. The floor beneath the gratings may be sloped (fig. 1) down to the open gutter; which will tend to bring the manure down to the opening, and facilitate the cleaning out. The plan of the floor is shown at figure 4; the reference letters being the same as in figure 1. This floor will be found very cleanly; the droppings which fall upon the gratings pass through them into the gutter; any which

Fig. 3.—CROSS-SECTION OF GRATED FLOOR.

may remain upon the bars is forced through by being trampled upon, and the cows' feet are cleaned by the action of the bars. No bedding is necessary upon this floor, and this expense is saved. This is an important item in towns and cities, where litter is very costly; and is, at least, worth considering where straw is plentiful, because the straw may be wholly used for fodder. Some dry earth, or swamp-muck, should be thrown into the gutter to absorb the liquid, and a daily dusting of finely-ground gypsum will prevent any odor from the stable. If the liquid manure is to be preserved separately, the gutter may be made to discharge into a cistern, and if the gutters and floors are washed down with water every day or two, a large supply of liquid manure could be secured. One of the Blunt Universal pumps, which is both a suction and force pump, attached to a cistern and furnished with a hose and nozzle, will be found very convenient for this purpose. The passage behind the gutter—when the room can be spared—should

Fig. 4.—PLAN OF SLATTED FLOOR.

be wide enough to permit a wagon or cart to be driven through for the removal of the manure; in which event, there should be doors made for the purpose.

A Method of Pulling Stumps.

A correspondent sends us a sketch of his method of pulling stumps or rocks, which may also be made useful in loading heavy logs, roots, or stones. The apparatus consists of a long stout pole, which serves as a lever; to one end of it is attached a chain con-

A CHEAP STUMP PULLER.

necting with the stump to be moved; to the other end the draft chain is made fast, a tree or stump being made use of as a fulcrum.

Gathering Clover Seed.

It is seldom that clover straw can be made useful after the seed has been hulled, so that it is a saving of labor, to cut it as high as possible, taking only the heads. By using the scythe, or cradle, this cannot be done; and it will be found much better to use a mowing machine, having a table attached to the cutter bar, or a clover-seed gatherer made expressly for this work. The former method is a convenient one, but it is only a makeshift after all. It consists in attaching to the cutter bar, a light frame of hickory slats, made somewhat like a set of cradle teeth, so that it will slide easily over the ground. A stout cloth is spread tightly over the frame, upon which the clover heads may be gathered as they are cut. A machine, of which the cutter bar can be raised several inches, if necessary, is preferable for this work. Then the clover heads only need be cut. As they are cut, they are raked back on to the cloth, until it is full, when the load is drawn off, and left in a heap to dry. The rake should be a sort of scraper, as teeth are unnecessary. A broad lath as long as the cutter bar attached

CLOVER-SEED GATHERER.

to the rod, is the best tool. A machine for gathering clover-seed is shown in the accompanying illustration. It is automatic, and does its own clearing of the teeth, by means of a revolving scraper, which is operated by the carrying wheels. The machine is guided by the curved bar behind, and drawn by one horse. The management of the clover seed crop is very simple. It is improved by frequent wetting and drying, as then the seed is more easily hulled, than when it is cured in dry weather. If the weather should be dry, it is best to rake the straw, or the heads, into small heaps, letting them heat moderately; afterwards spreading the heaps in the sun to dry. The raking may be done while still wet with dew, which will assist the fermentation, and heating, which partly rots the hulls, and helps the cleaning. The crop, when perfectly dry, after two or three weeks' exposure to the weather, should be stored in a corner of the barn.

The Pea-Fowl.

Although the pea-fowl is well known as a bird of fine feathers, few persons are acquainted with its natural history and real merits. It is a good table fowl, and as easily reared as the turkey, still it is rarely seen upon the farm or country place, and then only as an ornament. This bird is a native of

Asia, from whence have come nearly all our gallinaceous fowls, the turkey excepted. In the time of Solomon, it was an article of merchandise, and was brought with ivory and apes from Tarshish to Judea. One species of Pea-fowl was found by an English traveller, Colonel Sykes, abounding in a part of India, where large flocks were kept about the native temples. Another Eastern traveller relates that from 1,200 to 1,500 were seen by him in passes of the mountain, within sight at one time; and he speaks in extravagant terms of the brilliance of their plumage. There are three distinct genera, which include several species and varieties, such as: the Crested, the Black-shouldered, the Javan, the Japan, the Iris, the Thibet, the Malay, etc. All the domesticated sorts are surpassed by the wild ones in beauty. Cuvier says of the Pea-fowl: "We find in its incomparable robe, united, all the brilliant colors which we admire separately in other birds; we find all that glistens in the rainbow, that sparkles in the mine, the azure and golden tints of

Fig. 2.—FERRY AT HIGH WATER.

the heavens, and the emerald of the field." White, the naturalist, found that the feathers of the train do not belong to the tail, but that they grow upon the back, the real tail feathers being short, stiff, and brown, about six inches long, and serve as a prop to support the immense train. By a peculiar muscular action, the long train feathers can be erected and spread, and their shafts made to strike together, and produce a clattering noise. The Pied peacock is white upon the wings, belly, and breast; the rest of the plumage is as showy as in the other species. Pure white birds are very rare, and highly valued, but from the absence of the gorgeous coloring of the common kinds, they suffer greatly in contrast with the latter. It is not until the second year that the difference between the sexes becomes apparent. This bird lives from 20 to 25 years, and reaches maturity slowly. The third year the train of the cock becomes developed, and it is only when it exhibits its full coloring that he is ready to be mated with three or four hens.

The pea-hen lays her eggs on alternate days, and when she has produced five or six, she will incubate, unless the eggs have been removed. She makes her nest upon the ground, in a secluded place, beneath the shelter of low bushes, long grass, or weeds. The maternal instinct is well-developed in some hens: in others it is so lacking that they even destroy their own young, or leave them to perish from neglect. The period of incubation is from 27 to 29 days. The pea-fowls have strong local attachments, and they rarely leave the place where they have been reared and fed. They are sensible of kind treatment, and will become very tame when gently used and petted. They have a habit of roosting high, and will choose an elevated place on the top of the highest tree or buildings to which they can gain access. When but three days old, the chicks are able to reach a roost two or three feet high; and if they can mount from one step to another, they will follow the old birds to their highest roosting places. The birds are naturally shy, and their treatment must be regulated accordingly. The proper feed for the young pea-chicks consists of hard boiled eggs, cracked

wheat, coarse oat-meal, and bread-crums; and they will soon hunt after and consume insects and worms of all kinds. It is necessary to protect the young birds from wet and cold, and they require the same care which is needed for young turkeys.

A Small Ferry-boat.

We have a number of inquiries for a method of crossing rivers by means of a boat that can be

Fig. 1.—THE FERRY-BOAT.

drawn from one bank to the other by a rope. We suggest the following plan:—Set a post firmly in each bank of the river, and attach a rope to each post. Make a skiff, or scow, such as would be convenient, and attach a ring-bolt at each end, on one side, and have a winch with a grooved wheel at the middle, as shown at figure 1. The rope may be made to take one turn around this wheel, and by working the winch the boat will be easily drawn from side to side. When the current is swift during high water, and there would be a strong side pressure upon the boat, the following plan can be pursued, by which much hard work may be avoided. Two ropes should be provided, one fastened to each end of the skiff, and each fastened to the post upon either bank. When the stream is to be crossed, the forward rope is pulled until the boat is in the current, when it is made fast, while the other rope is left to run out as it may. The boat is, of course, carried down stream in a direction across the river until it reaches the opposite bank; when out of the strong current, it may be hauled up to the post and made fast. In returning, the same method is pursued.

An Egg Tester.

The accompanying engraving represents a contrivance for testing the freshness or fertility of eggs, useful in the household or to the poultry-fancier. It consists of

EGG TESTER.

shows a fresh or infertile one to be perfectly clear, while a fertile one that has been incubated two days will show the embryo, as in the engraving. Infertile eggs may then be taken from the nest.

A Cheap Pig-Pen.

In response to inquiries, we present a plan of a convenient pig-pen that will cost less than \$25, exclusive of labor. Nine posts of cedar or chestnut are set in the ground one foot, and projecting as far above the surface; arranged as in figure 1.

Sills of 4 x 4-in. are laid upon the posts, with a cross sill in the center, and halved together at the joints. No wall posts are used, the stout boarding being made to serve the purpose. The structure is 8 feet each way, or can be altered to suit the ordinary length of boards when built. To put up the walls begin at the bottom, fastening on the corner boards first and nailing their edges firmly together. Strips of 2 x 4 serve as plates. Floor beams of 2 x 6-in. are laid upon the sills, 16 inches apart, and the floor upon these. For a roof,

Fig. 1.—PLAN OF PIG-PEN.

rafters of 2 x 4-in. stuff are placed 4 feet apart, upon which three 12-inch boards are laid, one at the peak, one at the eaves, and one between these two. The roof boards proper, 8 feet long, are put on lengthwise of the rafters, and battened. Spaces for the doors and windows should be left or cut in the boards as they are nailed on. There should be two small windows, placed as thought most desirable.

Fig. 2.—VIEW OF PIG-PEN.

The interior division should be as shown at figure 1. The feeding place is at *a*, in which is a trough, with a sloping board in the passage, *c*, by which to pour in the slop. A sleeping-room is at *b*; the partitions of which should be 4 feet high. A few loose boards will be required for a floor in the loft to make a space for stowing corn for feed. The building is raised one foot from the ground for the sake of avoiding rats and other vermin. A sloping gangway leads to the yard; into which it is also convenient to have a gate from outside.

A Lock-up Nest Box.

It frequently happens that a nest box that will lock up is desired. Such a box may be made 3 feet square and 18 inches deep, which will be large enough for two nests. The door is at *a*. At *b* is a partition extending half through the box, and at the inside of this are two nests about 8 inches deep,

A SECURE NEST BOX.

16 inches long, and 12 inches wide. These are seen through the side of the box, which is partly removed for this purpose. For small breeds of poultry, the box may be made considerably smaller. Such a retired nest as this exactly meets the instincts of the hen, and it becomes very acceptable to her.

Farm Experiments.—There has never been so much experimenting by farmers as there is the present year. Great facilities for this kind of investigation have been given of late, and the tone of

the agricultural press has been such as to awaken an active spirit of inquiry in this direction. It is to be feared that some disappointment may occur by reason of unexpected failures to reach satisfactory results. Now, in experimenting, there is nothing so useful as patience. One year is far too short a time for a result that will be of any value. The results of experiments are useless, except as they are compared with each other, and it is of little avail to make trials and tests, of this or that, unless they are made methodically, and with great care, perseverance, and patience; and above all things besides, with the most accurate noting of all the conditions as to time, place, season, and other circumstances, as well as of the results. There can be no more valuable labor if properly carried through to the end than farm experiments, but if they should be abandoned after the first year, because the result may not be what was expected, they had better not have been begun.

Cultivator for Small Grains.

It is a well-known fact, that the cultivation and weeding of the wheat crop, largely adds to the yield. It is a usual custom upon the fertile English farms,

A GRAIN CULTIVATOR.

not only to hoe the wheat, but to pull every weed by hand that is not destroyed by the hoe. In this country hand labor is too costly to admit us to do this, but the necessity for it is so apparent, that farmers would at once adopt it if practicable means were provided. A very promising and quite effective machine for this purpose has been invented by Mr. A. B. Travis, of Mich., with which the writer has had an opportunity of experimenting. It is intended for the cultivation of any crop sown, or planted in drills, and we have tried it upon wheat, corn, and mangels. It is drawn by two horses, and it carries a row of teeth fastened to a frame which is loosely suspended to the axle so that it can be made to oscillate sidewise several inches. This renders it easy to follow the irregularities of the drills, and to avoid interfering with the plants in the rows. The teeth, shown in the engraving, are intended for working in small grains, wheat, rye, oats, or barley, and they can be moved to a less or greater distance apart, as desired. On the left of the illustration the form of the teeth is more clearly shown, a small one being used for wheat, and a broader one for corn, or roots. In using the cultivator for the latter crops, the center tooth is removed, leaving room to pass a row of plants without touching them, the remaining teeth being adjusted to very thoroughly clean the whole space upon each side of the row. Thus two rows are cleaned at each passage. In using this machine upon corn, this season, we cultivated the rows in two directions, the crop being planted $3\frac{1}{2}$ feet apart each way; and very little hand work was afterwards needed, although the ground was very weedy and the weather after planting was unusually rainy. The cultivation of wheat is, without doubt, an improvement greatly needed in our present practice. We need very much to make this crop more profitable. The present average is far too small. Instead of 10 or 15 bushels, it should average 25, and the best crops ought to reach 60 bushels in place of 40. With proper manuring, and freedom from weeds, we can reach the latter yield upon drained soils. If we could hoe the wheat, we might hope for an increase of 50 per cent in the yield, where the soil is sufficiently fertilized. If others do it, why should not we as well? We think we may reasonably look for success, and expect soon to have a wheat horse-hoe that will be cheap, effective, and that may also be used on the corn and

root crops, at least in their earlier stages, leaving the later operations to be performed by the plow.

Tethering Cows.

In pasturing a flock of sheep, or a herd of cows, upon a heavy growth of fodder, of whatever kind, the whole field will be traversed the first day, and a considerable portion be greatly damaged; but by confining the sheep within hurdles, or by tethering cows, the rest of the field is neither trampled nor soiled, and nothing is wasted. The herbage is consumed only within the limits of the tether, the remainder is left to grow until required, and the portion pastured soon regains a fresh growth, and is evenly manured at the same time. By tethering, we acquire all the advantages of a system of soiling, without the labor of cutting and carting of fodder, and of hauling the manure made in the yards—that is, if the droppings are evenly spread over the field, as they should be, and not permitted to remain in patches. By the use of the tether-pin illustrated below, cows can be confined within proper limits without risk of winding up the chain on the pin. The swivel-ring upon the top turns as the chain is drawn around, and as the head is pressed down close to the ground, there is nothing upon which the chain can wind. In using the tether, it is a good plan to advance the pin each time to a sufficient distance in a direct line, thus feeding off a strip through the field or plot of ground. When such a strip has been eaten down, begin again next to the first starting point. In this way the grass is eaten off regularly, and when the field has been all fed off, it may be gone over again. Where a number of cows are tethered out, they may be ranged in a line, and made to advance regularly through the field. If the herbage is dense and tall, a half circle of twenty feet radius would be nearly sufficient for a cow for one day, so that the pin may be advanced the length of a twenty-foot chain, only,

TETHERING-PIN.

each day. A very near estimate may be made as follows: A crop that will produce $1\frac{1}{2}$ tons of hay will cut six tons of green grass, which is equal to about a quarter of a pound to a square foot. A cow will consume 80 lbs. of fresh grass per day; hence, 240 square ft. should supply a cow with one day's fodder, which is equal to a space of 20 ft. long by 12 wide. In this way the space fed off may be accurately apportioned. If the grass is about half grown, twice 240 square feet would have to be allowed, in which case the pin should be moved ahead at noon each day, and so of other yields.

A Wooden Stable-Fork.

The writer has recently seen and used a stable-fork made of wood. For use in arranging litter about horses and cows, and in lifting fodder, whether whole or cut into chaff, it is very convenient. As the points are not sharp, the danger to man and beast, incident to the steel fork, is avoided, and it is much lighter to handle than a steel fork. The engraving given in the next column sufficiently describes the implement.

Our Foreign Markets.—The extraordinary increase in our foreign exports, chiefly of Agricultural produce, by which the balance of trade has been made to fall in our favor to the extent of more than \$250,000,000 during the past year, has had a very beneficial effect upon business. It has prevented the export of gold, and has greatly helped to keep up prices. It has been this foreign demand which has eased the provision market, greatly depressed by a production of meat, much in advance of that of any previous year. Fortunately

we have been able to open new outlets for our products, and these once gained, will be likely to become permanent. Heretofore, Great Britain has been the chief customer for our grain, meats, and cattle, but recently a live cattle trade has been opened with Germany, and shipments of beef, pork, and mutton, have been made to France. The consumption of meat is rapidly increasing and out-

MANURE FORK.

stripping the production in France. There is no other source of supply for that country more convenient than the United States, and the probability is, that we shall be able to secure the greater part of it. For the last three years, France has increased its imports of provisions to the extent of over \$30,000,000 annually, taking \$207,600,000 worth in 1877. Her imports of cattle for the first three months of the present year, exceeded in value \$7,200,000; the number of animals being over 400,000; of which 315,000 were sheep, and 49,000 swine; thus in one year that country needs to purchase a very large number of live animals, in addition to the supply of meat, both fresh and cured, and fish. To secure this market it is necessary to furnish desirable grades of animals. At the present, we are most deficient in our supply of mutton sheep, in which respect we are slowly improving, but it is essential that we lose no time in raising the character of our live stock, so that we may be able to meet the demands of those who will willingly become our customers. The bulk of this foreign trade in live animals would naturally fall to the share of the Eastern parts of the country, which are near the shipping ports. No other section needs more the good effect which feeding stock must produce upon its system of agriculture than does this; and none can make the business more profitable.

Country Parsons.

In former times the English country parson was the best farmer in his parish, and set the example in the use of improved implements and methods of practice. He was looked up to as a guide in temporal things as well as spiritual; and his care of the material interests of his flock gave him better knowledge of their moral wants. To-day, the farming parson has largely given place to the pale-faced dispeptic who shuts himself among his books, and knows and cares little for the every-day affairs of his people; but specimens of the old stock are still found in rural England, and the name of a rector or vicar is often seen in their agricultural papers, signed to able writings on theory and practice. In America the farming parson is a scarce personage, though examples are not wanting. The author of the genial "Tim Bunker Papers" is an excellent farmer, as well as pastor, and is held as a safe authority by his neighbors in things agricultural. Even Mr. Beecher wrote a book on gardening, and if his lot had been cast in a country town, he would have been a great agriculturist. A score of such might be cited; but many readers will have some public-spirited, wide-awake village minister whom they would set up as an example to their own spiritual directors.

We need more farming parsons. The country clergyman, if he would exercise the greatest influence among the people, must take more interest in their crops and herds; *he must have crops and herds of his own*. His mental training should fit him to be a good observer of nature, and of methods of practice. His opportunities for study of books and papers should enable him to keep posted on all the progressive ideas and methods of the day. The farmer needs all the precept and example—particularly *example*—in good agriculture that he can get. The country clergyman has such influence that he may do agriculture an incalculable amount of good; and if he will mingle more of nature and everyday

life in his Sunday sermons, he is sure to make them more acceptable and effective, than when all composed of the text, precept, and theory of books.

If not satisfied with the examples of success in this line among his acquaintances, let the parson turn to his beloved tradition. Even the Head of the Christian Church taught by practical labor as well as by oral moral precept. The monks of the middle ages were the preservers of the best of agriculture of the earlier times for those who came after the dark ages had passed; in them was possessed all the farm lore of that day. And history tells us that for long years thereafter the clergy were the pioneers in agricultural progress. The spirit and thought of the people, and the needs of the calling for men of thought engaged in its work, open to the country minister an inviting field, and a promising harvest of increased influence.

How to Kill Quack Grass.

The writer has been engaged for two summers in eradicating this pest from fields of corn and potatoes, and the ground, until recently, was apparently as full of roots as when the work was begun. Ordinary cultivation does not seem to have any effect on it. We give in next column an illustration of the plant, by which it may be readily recognized. It will be observed that the grass has a long-running root-stalk, with roots springing from it at very short intervals.

Buds, one of which is seen at *a*, start from the root-stalk, so that if it be cut into small pieces, each bud will send up a shoot, and form a plant, which in turn will spread in the same manner. The spike (seen at the right) has its spikelets arranged as in wheat (*Triticum vulgare*), with the flat side towards the stem. Its manner of growth renders special treatment necessary to destroy it. Two methods may be used, in conjunction or separately: one is to employ a cultivator with teeth, made as in fig. 2, having an edge of steel that can be ground sharp. This should be run about an inch deep, when it will cut off every shoot, leaving the root intact. If this is done frequently through the season, our experience is that the roots die in time, their vitality being exhausted in the effort to throw up new buds. The other is to use a cultivator, or grubber, with teeth similar to those shown on page 256 (July), fig. 6. This tears out the roots, when they may be gathered and burned. It is not safe to throw them aside, as they will sprout after the first rain, and send out new roots into the ground.

Village Improvement.

BY E. W. B. CANNING.

The Laurel Hill Association, of Stockbridge, Berkshire Co., Mass.

This Association had its beginning in the year 1853, and was set on foot entirely by the efforts of one devoted lady—now Mrs. J. Z. Goodrich—whose personal and untiring labors to arouse the people resulted in an organization which has not only secured to the town incalculable benefits, but has become the inspirer and the model of similar associations in other States. [An account of a more recent effort of this kind was given in February.]

After a thorough canvass of all portions of the town, by way of preparation, a meeting was held in August, which proved an enthusiastic success. Besides its own citizens, many sons of the town, settled elsewhere, were present, or responded by the proxy of a liberal subscription. All the preliminaries of a regular organization under the General Statutes of the State, were transacted. By its constitution membership was obtainable by an adult on the payment of \$1, and of 25 cents by a child, or, on the part of the latter, by the planting of a tree under direction; and every child was en-

couraged by this means to erect a memorial of him or herself, to bear thereafter the name of the planter.

A remarkable knoll, where magnificent rocks are overhung by a forestry of oaks and pines, was purchased some years previously and presented to the village as a pleasure ground, by a public-spirited citizen. An abundant undergrowth of Laurels, suggested a name for the locality, and also the name of the Association. An aggregate of about \$1,400 in cash and available subscriptions enabled it to commence operations with vigor. Its attention was primarily directed to improvements upon this hill; then extended to the village cemetery, whose ruinous fence was replaced by a tasteful structure of marble and iron, within which, a year or two later, was set a hedge of Norway Spruce. The latter is now kept about 15 feet in height, and is a superb wall of perennial green. Within this enclosure walks and drives were con-

QUACK-GRASS (*Triticum repens*.)

structed, shrubbery and trees planted, leaning monuments set perpendicular, and provision made for repeated mowings. Then the streets of the village were taken in charge; sidewalks straightened, trimmed, and gravelled; crossings laid; gutters constructed with regard to thorough drainage, and shade-trees set along the sides of every street. Year after year these improvements were pushed farther, and along the roads leading into the town, and the opportunity for pedestrian exercises greatly enlarged. In undertakings involving more expensive labor—such as grading and working the roads through and near the village—the Association has acted in concert with the municipal authorities, adding its own to the town's appropriation, and thus securing a direction in the enterprise. The two have thus enjoyed mutual aid, to the invaluable advantage of both.

The question is often asked us, Were there no opponents of this crusade of improvement?—Yes—but they were not numerous, and no long time was required to conciliate them entirely. It is not in human nature, when one puts his premises in order and beautifies them with taste, for his next neighbor to endure for long the contrast suggested by the neglect and dilapidation on his own premises, and the chances are that he will not only not only fall in with the prevailing spirit, but become a formidable rival in betterments with the

other. The little labor and trifling expense necessary to effect a change in his surroundings, of which, when made, he can not but be proud, ere long convert him from a brake to a spoke in the wheel of progress, particularly when he comes to find—as he will—that there is money in the operation.

Once a year, in the month of August, our Association holds its festival on Laurel Hill. A turf rostrum built against a huge overhanging cliff is the nucleus of operations. On that rural platform sit the officers and invited guests. Around and in front, beneath the shade of the oaks, on the level plat that once formed the Council-ground of the Housatonic Indians, stand or sit the town's people; the numerous summer sojourners and visitors from the neighboring towns, whom the occasion attracts, forming an appreciative audience, sometimes of several hundreds. After prayer (and often music also), the choice of officers, and the annual Report of the Executive Committee, an oration is pronounced—usually by some distinguished native of Stockbridge—which is supplemented by brief offerings in prose or verse, and extempore speeches from visitors. After some two hours of these pleasant exercises, the occasion is closed—at times with a dance by the young people on the verdant sod, to the music of the band. This is peculiarly the village festival, and tends to keep alive and transmit the influence of the institution to which so much pleasure and profit are due. In the course of its existence of 25 years, the records of the L. H. Association show an expenditure of \$6,692, with the following as some of the results:

1. The acquisition by legacies of more than \$4,000, most of which has been invested in public funds; the revenue from this, with the annual subscriptions, affords available means and secures the permanency of the Association.
2. The setting of 1,686 trees, besides several hedges. These, from mere saplings have become magnificent specimens to afford a grateful shade and be the joy and pride of coming generations.
3. Well ordered streets, sidewalks, gutters, and crossings, rendering locomotion convenient and agreeable at all seasons.
4. A general tidying up of all the private dwellings and premises throughout the community, rendering ours, externally, the finest village in Western Massachusetts—the subject of admiration by all visitors and sojourners.
5. The growing education of our people in the beautiful in nature, aided by art, tending to diminish rudeness, and to the promotion of morality.
6. An increased value of real estate of from 20 to 100 per cent. Trees planted by the Association in its infancy in front of some humble premises, have, on the acknowledgment of a later purchaser, added \$500 or \$1,000 to his offer therefor. Seldom is a larger income returned from so small an outlay.
7. An example which has been copied by scores of communities that have obtained our constitution as the foundation of similar organizations in distant localities. Such applications continue of frequent occurrence.

Emasculate the Dog.

With few exceptions, there is no place for the dog in agriculture. His ravages among the flocks in many places are an insurmountable bar to sheep keeping, rendering, as it does, so costly a watch over the sheep by night and day as to swallow up the profits. What can be done about it is not so clear. Those who wish to have dogs can hardly be prevented, and the impossibility of keeping the animals under control is evident. So is also the difficulty of recovering compensation for damage where the law provides for it, and the undesirableness of constant and costly litigation for this end, which is a poor remedy, even if successful. We gladly noticed in a recent article in the "Forest and Stream," a suggestion, which seems to be practical and practicable. It is simply to bring these animals under the same control which is effective in restraining others, viz., to cause all male dogs, except those kept for breeding, to be emasculated, and to suffer none others of this sex

to go at large. In this way the present overwhelming increase of the race would be stopped

crops, and clover, is yearly widening; and that under cotton at the same time is only slightly diminishing; thus leaving the cash crop, nearly, if not quite, as productive as ever; but rendering the expenditure for food and fertilizers, very small, or completely avoiding them. But it is always safe to have two things to depend upon, so that if one fails, the other may remain, and wool is precisely a companion crop for cotton in this respect. Besides, with wool there is mutton, which is a food crop, and sheep manure is of the richest quality.

Wool is always salable, and is the staple of a large home manufacture. It is worth more in many places, at a distance from the seaboard, than on the coast, if there are mills in the locality to work it up. Mutton and lamb, if of fair quality, are always salable to the local butchers, and provide a very agreeable fresh food for the farmer's family. Sheep will thrive excellently in the Southern States. There are vast tracts of land, notably, the pine woods and table lands of Western Georgia, the Carolinas, and Eastern Tennessee, which are unsurpassed as cheap sheep-walks. In the South, sheep require less feeding in the winter, than in any other part of the country, California excepted, perhaps. Root crops may be grown and fed off from the ground by a "penning" system, and thus the soil be richly

and cheaply fertilized and prepared for cotton or corn. Large tracts of adaptable land, can be

furnish excellent pasture for sheep; among these are the so-called Wire-grass, Bermuda-grass, Crab-grass, and Broom Sedge. Other plants of an astringent and resinous character grow in the old fields and pine woods; and Blue-grass of the best kind grows abundantly upon the table lands. From ample experience, it has been found, that fine wool, and wool of the common Merino crosses, can be grown very profitably in the South; flock owners of large experience, have rated the cost of growing wool under the most favorable circumstances, as low as 6 cents per pound. The climate enables the raising of early lambs for Northern markets, to be carried on with the greatest facility; and the easy communication with the North, as well as markets of the South, ensure a ready sale of the products.

The Aconite-leaved Geranium.

It has more than once come in our way to state that the plants popularly known and cultivated as Geraniums, did not belong to the genus *Geranium* of botanists, but were classed as Pelargoniums. There are differences in the structure of the flower distinguishing *Geranium* from *Pelargonium*, which need not be given here; besides these, the Geraniums are, with very few exceptions, herbaceous plants, while the Pelargoniums, as a general thing, make woody stems. We have several native species of *Geranium*, notably the Cranesbill, which is common in all the States west of the Mississippi, and is well known for its remarkably astringent root, much used in domestic medicine. The European *Geranium sanguineum* and one or two other species are not rare in collections of herbaceous plants, where they are valued for their compact habit and abundant bloom. The species here figured, *Geranium aconitifolium*, the "Aconite-leaved Geranium," is a native of Switzerland, and is interesting as an instance of the renewed popularity of a very old plant. It was introduced into the gardens of England over a century ago, but it is only recently that its remarkably fine foliage—which has the shining green of the Aconite, from which it is named—and abundance of bluish purple flowers, have attracted attention. It is now regarded as a useful hardy bedding plant in England, especially for its early and abundant bloom. We are not able to testify to its hardiness here, but have put out a row as a margin to a bed, and expect to be able to report that it has survived the winter. At any rate,

THE ACONITE-LEAVED GERANIUM.—(*Geranium aconitifolium*.)

at once, and the cruelties practised by the lawful "dog catchers" be avoided. At present we permit an indiscriminate multiplication of dogs, and annually carry on a war of extermination against them, at great cost and suffering. This is simply making trouble for no purpose. There is a growing disinclination amongst farmers to keep a dog of any kind, and the great majority are preserved solely to gratify the desire of the children to keep a pet or a companion. If the law which applies to male domestic animals of other kinds were brought to bear upon dogs, and these were restrained just as rams, boars, bulls, and stallions are, there would be a prospect that the evil would essentially diminish.

Sheep Farming for the South.

Exclusive cotton growing is an unsatisfactory business. It has brought many planters to bankruptcy, and more into debt; and the advice is given, "raise corn, grass, anything but cotton." The *American Agriculturist* has for many years advocated the growing of a variety of crops in the Southern States, to such an extent as would involve all the planters capital and attention. First, food crops; then crops to consume upon the farm, and then crops to sell, is a judicious system of management. The Southern farmer then has food, meat, manure, and money; and in this case, the money is more apt to stay with him than that procured by the sale of cotton, from which is deducted the cost of fertilizers, food, interest, etc., and a very small balance, if any, is left for the planter and his workmen. It is encouraging to note the change which has occurred of late years' in this direction, and the consequent improved condition of the farmers. The acreage under wheat, corn, oats, grass, fodder

cheaply procured in many parts of the South. There are several varieties of wild grasses and other plants which grow spontaneously, and which

should it fail to be hardy, it is an admirable plant for a cool greenhouse, both on account of its fine foliage, and the abundance of its lively flowers.

THE FOREST ROSE.

New Strawberries of Promise. "Crescent Seedling" and "Forest Rose."

BY E. P. ROE.

Though far from being a veteran in small-fruit culture, I have already become convinced that Nature does not concentrate every excellence in any one variety. As with our circle of acquaintances, so it is with our lists of fruits, we cannot dwell on the character of even the best of them without recalling faults as well as good qualities. We must bear with our friends' foibles, if for no better reason than that we are in need of forbearance ourselves; but we are under no obligation to enumber our gardens and fields with old acquaintances in the way of fruits, if new and better ones are to be had. If one might judge from the catalogues sent out, it would seem that the public were offered a dozen or more perfect strawberries every year; but in most instances, these new seedlings appear to be like the small children that astonish the home circle, but make little or no impression on the world at large.

The two strawberries that head this article promise to be marked exceptions to this rule. Their promise in the localities where they first appeared, has been so far fulfilled in my own grounds, that the Editors of the *American Agriculturist* feel warranted in asking me to "report progress." Mr. T. B. Pope, of Newburgh, N. Y., an artist well-known for his excellent delineations of fruit, made accurate sketches from clusters of these varieties. Each berry was drawn from actual measurement, the aim being to represent the average size, instead of to mislead by presenting a few unusually fine specimens.

I hardly know what to make of the "Crescent Seedling." It has been called the "Poor man's Strawberry." I think that it might be called more aptly the "Lazy man's Strawberry." As I have seen it growing and bearing this year, it would seem that the picking of the fruit was the only labor worth naming involved in raising this berry; but this item of picking will go far toward making up for what is lacking in the work of cultivation. The two marked features of the "Crescent Seedling" as I have seen it in several localities are: a tendency to take entire possession of the ground—crowding out the weeds as the northern tribes shouldered weaker races aside—and of literally covering the ground they grow on with fruit. It is claimed that it will yield at the rate of 15,000 quarts, or about 470 bushels to the acre. This seems incredible, and as yet I do not believe it to be possible under wide and general culture. If it will yield 300 bushels to the acre, under good treatment, it will, in the estimation of many good judges, work a revolution in strawberry culture. The case has been stated to me in this form: "Any farmer, with ordinarily good corn land, can set out an acre or more of this hardy, prolific berry, and flood the market with the fruit. Therefore, the raising of strawberries will become unprofitable for those who make it a specialty."—I do not believe this.

Fine fruit will always bring a good price; and no variety will produce *fine fruit* under slovenly culture. The market will be "glutted" with small soft berries; and the "Crescent" will, I think, be both *small* and *soft* if allowed to mat the ground with plants, according to its tendency.

Its lack of firmness—of good shipping qualities—will, I imagine, prove its chief fault. I would advise growers—especially those near to markets—to plant it liberally, but on no account, as yet, to abandon the "Wilson" and other varieties that have proved profitable for many years. I know the *American Agriculturist* will endorse my warning against putting "too many eggs in one basket," especially a comparatively new and untried one. The "Crescent" originated with William Parmelee,

from one season's observation, the "Crescent" ripens about the same time as the "Wilson," and so is one of the earliest varieties.

The "Forest Rose" is decidedly different from the "Crescent" in many respects, and surpasses it in flavor, beauty, and especially, in its shipping qualities. I doubt whether we have a berry better adapted to long carriage. But thus far it has not proved with me anything like so productive as the "Crescent." It is but another illustration of the truth that all the good qualities are never found in one berry. I exhibited the "Forest Rose" at the Queens Co., N. Y., Fair, this summer, and it took one of the 1st premiums, and was greatly admired. It suffered less from transportation than any one out of 36 varieties I exhibited there. I am grow-

ing it on three kinds of soil—the stiffest kind of clay, a light, moist soil, and a gravelly knoll—and it is doing well in each instance. The foliage thus far, with me, has never turned or rusted. The most emphatic way in which I can make known my hopes in regard to it, is to state that I planted it more largely than any other kind last spring.

It is a chance seedling, and was discovered by Mr. J. A. Fettes, of Lancaster, O., while hoeing in his vineyard, about seven years ago. Mr. Fettes sold out his right in the seedling to Mr. Leo Weltz. So eminent an authority as Dr. J. A. Warder, after visiting the original plantations of the Forest Rose, made a report to his Society as follows:

"This new strawberry promises, indeed, to be a great acquisition to our stock of varieties. For a long time, 'the Wilson's Albany' has borne pre-eminence as a market berry—for which purpose it is indeed admirably adapted—but cultivators have desired something even much better in quality. Here we have *elegance of form, brilliancy in color, great size and firmness to bear transportation*, all combined with *table qualities* of a higher order than in 'Wilson's Albany', which it surpasses even in

THE CRESCENT SEEDLING.

Esq., in New Haven, Conn., in 1870, and was sent out by Mr. H. H. Smith, of West Haven, Conn. Mr. Smith has been very fair and open in asking all to come and see and judge for themselves, and the berry has really made its way on its own merits. I have seen it growing vigorously and fruiting enormously on light New Jersey soils, for I took pains to see it in four different localities. In some instances, other and leading varieties standing near it had proved utter failures. It has also done remarkably well on damp and heavy soil in my own grounds. The cluster here represented, was from a potted plant set out last autumn. The engraving gives the shape and habit of growth. In color, it is a bright scarlet, and looks well in the baskets. Like the "Wilson," it is red before it is ripe, and in this *immature* state the *flavor* is *poor*, but greatly improves as the berry ripens. It has the appearance of being a "pistillate," although it is claimed that it will bear alone. I noticed, however, that in a field of four acres owned by Mr. Smith, "Wilson's" were planted at intervals, and I would advise that some perfect flowered varieties be set out in the same field or garden. As far as I can judge

field culture. When the enthusiastic proprietor invited some of his friends to visit the plantation to see the *largest strawberry in the world*, the expression was received with a few grains of allowance, and was attributed to the warmth of an over-sanguine owner of a very good strawberry; but after a thorough examination of the bearing plants in different situations, the conclusion was reached that the Forest Rose was at least one of the *very best strawberries known*.—Dr. Warder is excellent authority.

The claims of these comparatively new varieties are presented to the readers of the *American Agriculturist* that they may have a chance to work the mines before they are over-crowded or exhausted. I may seem an old fogey when I say, that while I shall give these plausible strangers plenty of room in which to prove their merits, I shall still stand by my old and tried friends in the strawberry field.

Layering the Strawberry in Pots.—It is not too late for those who would make the most of a rare variety, or who have a small bed and would make a large one to come into fruiting as soon as

possible, to strike the runners in pots. This method, while it can not be profitable in field culture, allows the amateur to save a year, if he will take the small amount of trouble it requires. Small flower-pots, two or three inches in diameter, are filled with rich soil; plunge these into the soil of the bed, each directly under an unrooted runner, or rather the bud of a new plant at the end of the runner—setting the pot down in the soil of the bed up to its rim. Place a small clod, or stone, or forked twig to hold the runner in place upon the soil of the pot, and it will take root in two weeks or so; the connection with the old plant may then be severed, and the new plant turned out of the pot and set in the new bed without any disturbance of the roots. If set this month, well cultivated, and the runners kept off as they appear, a very fine crop may be expected next spring. The layering should be done at once.

Notes from the Pines.

In a fairly large collection of ornamental shrubs, I know of none that is more desirable than the

Double-flowered *Deutzia Crenata*.

I refer to the shrub first introduced under that name, and which has been in our collections for several years. In the first place, it fills a gap, by coming along just after the *Weigela* and other early-blooming shrubs have done flowering, and makes its display about the middle of June. It first gives us a few days of promise, and these show the outside of the petals with a most charming tinge of purplish rose. The few days it remains in this state, are, to my notion, the best; but it after this comes into full flower, and the bush is a sheet of white, as by opening, the interior petals quite hide the outer colored ones. After this excellent shrub had become well established, the nurserymen offered, with some flourish,

Deutzia Crenata flore alba pleno,

which, being interpreted, means the White Flowered Double *Deutzia crenata*. This has flowered with me this season, but is in no respect preferable, indeed, not equal to the older variety. It is true that the flowers are pure white throughout, but give only pure white, while the older kind gives us both the purple-rose tinge before it fairly opens, and at length as good a white as the other....In former notes I have mentioned our

Native *Wistaria*,

Wistaria frutescens, as a much neglected climber. It does not flower until the vine is in full leaf, and its flowers are not so large or of so deep a purple as the more generally cultivated Chinese species. It is for the very reason that it flowers later that I value it. The Chinese is good in its way; still, if I could have but one, I should take our native, as it gives foliage at the same time with the flowers. Having cultivated the ordinary purplish-flowered form, and also the white variety for several years, I was quite surprised to find, in conversation with horticultural friends around Boston, to learn that

The White American *Wistaria*

was quite unknown at that center of horticulture. This led me to "hark back" on the plant, and trace its origin. I found that my vines were sent me, the season that I came to "The Pines," with a very generous contribution of other hardy stuff, from my not very distant neighbor, A. S. Fuller, Esq., and that he procured his original plant from W. R. Prince, of Flushing, who had in his time a most remarkable collection. Beyond this it is not possible to trace its history; but those who knew Mr. Prince in his younger days, are aware that he spared no pains in procuring any new and strange plant that he might hear of, in any part of the country....Several years ago a gentleman in Tennessee (I think) sent me some small trees of

The Dyehouse Cherry,

so called because it originated on the place of a person by the name of Dyehouse. When they came, I, to save them, put them in temporarily where they grew a year or two, and were then set out where they were to remain. This is the first year that they have borne anything of a crop, and

though the trees are not over 6 or 8 feet high, they were fairly filled. The fruit was ripe at least a week or ten days before the "Early Richmond," heretofore the earliest cherry I had, and while about the size of that, is a palatable fruit. The "Early Richmond," even when dead ripe, is, to my taste too sour for anything but cooking.... It is curious to see how flower-fashions run. I can recall cases in which the *American Agriculturist* was the first journal to describe and figure a plant, and I may say the same of the "Gardener's Monthly." The plants, whether of native or foreign origin, have been presented to the horticultural world in these American journals for the first time, at no little trouble on the part of the editors, to procure and grow them, and at considerable expense on the part of the publishers, in giving excellent, and original engravings. Yet, what good does it do?—It is only when these same plants, years after, are brought out in European publications and in the catalogues of European cultivators, that our growers become aware of such things. It would seem that our people can not appreciate the value of a plant unless it has been first endorsed abroad. As long ago as 1868, I saw a bed of

The Japanese Iris (*Iris Kämpferi*)

in the garden of James Hogg, of New York City. The plants had been sent by that most excellent horticulturist, his brother, Thomas Hogg, then a resident of Japan. After they had been in the garden of James Hogg sufficiently long to show that they were perfectly hardy, I, in October, 1870, gave some account of them, with an engraving, considerably reduced in size, it is true, but sufficient to show their great beauty, and how unlike they were to any heretofore known forms of cultivated Irises. Within these few years the Japanese Irises have been introduced into European gardens, have been figured in European journals, and now our dealers have found out, from across the water, how fine they are, and offer them as novelties. Having cultivated them these 8 or 10 years, I can endorse all that the dealers say of their beauty, and hope that they may be as well known as their merits deserve. In the first place, they come into flower after the ordinary garden Irises have done blooming. The flowers are quite unlike those of the ordinary garden varieties, as they spread out in a flat plate, and are seen at their best when looked down upon. They are from four to six inches or more in diameter, and present a great variety in form, color, and marking; there are pure whites, pure blues, and those of the richest imaginable royal purple. In the way of marking, there is the greatest imaginable variety. Nothing can be richer than some of the intense purples and blues with lines of golden yellow, or more delicate than the whites, with net-work of blue and purple, and *vice versa*. With such a marked tendency to vary, no doubt seedlings will be raised finer, if possible, than any we now have. European growers are astir with this Iris, and I am glad to know that Mr. Thomas Hogg, who has introduced so many choice Japan plants, without claiming the least credit, has selected the choicest of his importations to which, as will be seen elsewhere, he has given names and descriptions, and has placed them in the trade, where they will be accessible to those who fancy choice plants....Sometime ago, in speaking with Prof. C. S. Sargent of a brother horticulturist, he remarked, "he knows a good thing when he sees it." I have more than once had occasion to think the same of Prof. Sargent, who not only "knows a good thing when he sees it," but he also takes care that others shall know it, by freely distributing, as well as talking about it. Among the plants that he has been instrumental in thus popularizing is

Hall's Honeysuckle (*Lonicera Halleana*).

In the general confusion in which the genus *Lonicera* is at present, I will not undertake to say to which botanical species this belongs, but as it is in several catalogues as *Lonicera Halleana*, there can be no difficulty in getting it under this, its horticultural name. Any one "who knows a good plant when he sees it," can not fail to appreciate this as a most valuable climber. Its lithe slender stems make it a most manageable plant. I have it growing

flat upon the ground, and running up upon what is part fence and part trellis, and also in pot culture. It is one of those easy-going things that will grow anywhere, and bloom whether 2 or 20 feet high, and—what is more to the purpose—keep on blooming. It blooms right along, all summer. Its flowers, when they first open, are of the purest white; a little while later they are of a delicate buff-color, and before they are done with, become darker still—almost an orange-color. All the while they have a most pleasing perfume. In some former talk I have said something about

Wire-Work on the Veranda

to the effect that one could decorate his veranda, or portico, as he pleased, without having the wire in contact with the woodwork. Serew-eyes of galvanized iron, 4 to 6 inches long, may be had at the hardware stores, and with these and galvanized wire, No. 14 or 16, one can build a framework upon which such vines as Hall's Honeysuckle can be trained, and keep the vines from actual contact with the wood-work, while they appear to completely clothe it....Early peas are for the most part unsatisfactory for their shortness of bearing, the best of them giving but two pickings, at the most. This is all well enough for the market-gardener, who wants his crops all at once, and then can clear his ground for something else. Generally no crop is so unsatisfactory as *early peas*. There is the trouble of sticking, picking, and other time-taking work, for a mess or two. With later peas, like that good old stand-by, the "Champion of England," it is different. One can pick, and come again and again. I had about come to the conclusion that early peas were more plague than profit, when this season, finding "Early Peas" on my memorandum, I asked Mr. W. H. Carson to give me some of his best early peas, leaving the choice to him. I thought no more of the matter, until the peas came to the table. We had, of course, at first some strain of "Daniel O'Rourke," early, and peas, but calling for no comment. Then came peas that *were* peas, and on inquiry I found they were

Kentish Invicta,

with the remark that they were a great cropper, and held out remarkably well. Seedsmen make a point of five days, in the earliness of peas, but I had rather wait twice five days, and get peas like the "Kentish Invicta," than to bother with such flavorless things as the Daniel O'Rourke, by whatever name it may be called—and it has a dozen or more.

Quinces and their Cultivation.

Why is it that the Quince, which is as hardy and as well adapted to our soil and climate as the apple, is comparatively scarce, and commands on the average three or four times as much in our markets? There is seldom, if ever, a "glut" in the market, and prices are uniformly remunerative, bringing the producers for handsome fruit from \$2 to \$4 a bushel, in New York and Boston, almost every season. The apple, in the fresh or dried state, enters into the annual supplies of almost every family, as cider, vinegar, jelly, sauce, and other preparations, and is also a profitable feed for our domestic animals, while not one family in ten knows anything of quince preserves and jellies. It is really one of the most appetizing and wholesome of the sweetmeats found among the stores of our housewives; and the cultivation of this fruit should be greatly extended. We know of no fruit that promises so good returns as this to the intelligent fruit-grower. If we look at the quince plantations, as we ordinarily find them, they are few and far between in the farming districts. The popular fancy is, that the bush flourishes best in a damp soil, and if there be an undrained swale on the premises, we may safely look for the quince bushes there. More frequently than otherwise, they stand in the grass, receive no cultivation, and after a few brief years die, either from stagnant water, or the attacks of the borer. Under such treatment the trees have no chance to bear fruit, and make themselves profitable. The quince wants a deep, rich, rather moist soil, but it should always be well

drained. Good corn land, that will bear maximum crops of grain, will bear good quinces. No fruit pays better for thorough cultivation, and the ground should always be kept under the spade or plow, and should, if we want abundant fruit, receive a good dressing of manure every season. The bush, or tree, requires very little other care than the occasional thinning out of the branches if they crowd too closely. The binning of the fruit, where it sets too abundantly, will increase the size and profitableness of the crop that remains. The fruit, as well as the flower, is quite ornamental, and an attractive feature in October and November. The "Apple," or "Orange Quince," is by far the best variety. It ripens earlier, and brings the best price in the market. The quince is easily propagated from cuttings, and this is the simplest and best method of multiplying a desirable variety. Cuttings put down in the spring, in a moist, well drained soil, a little shaded, will root about as readily as the currant. In making a plantation, the young trees should be set at least ten feet apart, and if the soil is rich, fourteen feet will be none too much.

CONNECTICUT.

[Our correspondent anticipates our intention to call attention to the importance of this much neglected fruit. We give his article as introductory to others we had in mind, going more into details of the culture. There is one point on which we would like information. We have, as hundreds of others have, a dozen or two quince trees, set here and there in by-places. They, situated as they are, seem to be profitable. Has any one of our readers tried an orchard solely of quinces? If so, will he tell us something about their culture in this manner, what are the difficulties in and chief obstacles to the success of an orchard of quinces, and what is the average profit per acre of such a plantation? These are points upon which many would like information. We know all about their hap-hazard growing—for it can hardly be called cultivation—but who will tell us about "quince culture for profit?"—ED.]

Okra—Gumbo.

Okra is a vegetable that is slow in finding its way to the garden and the table in the Northern States, while in Southern families it is in very general use. The plant is much like a large Hollyhock, with yellow flowers, which are succeeded by angled pods, six inches or more long, and over an inch thick. These pods, when so tender that they will break, are very mucilaginous, and give off, when cooked, a large amount of gummy matter. If they begin to mature, they become woody, filled with hard round seeds, and quite unlike anything edible. Though in the catalogues, the plant is called "Okra or Gumbo," the name Gumbo properly belongs to the dish prepared from the pods, rather than to the plant itself, as the Southern cooks make Gumbo without the use of Okra, but substitute the pith and young leaves of sassafras, one of the native violets, and perhaps other plants. The best Gumbo is made with chicken, though veal and other meats are sometimes used, and is merely a stew made thick by the use of an abundance of Okra pods. Gumbo soup is any soup to which sufficient Okra is added to give it the desired thickness. The young and tender pods, boiled and dressed with melted butter, are liked by many, but they are rather too gummy for those who have not become accustomed to them. A dish made of the Okra pods and tomatoes stewed together, is also prepared. One correspondent inquires if we know of any method of preserving Okra by canning. We have not known any attempts at canning the pods, but they are often dried; the pods of the proper age for cooking, are sliced, strung upon a cord, and dried in the same manner as fruit. They are also packed in salt, just as cucumbers are, and when wanted for use, are freshened in cold water.

What May be Done with a Soap-Box.

—The writer's first propagating house was a soap-box—hardly this, for it had neither cover nor bottom. It was the frame formed by the four sides, and over either the top or bottom—which, is imma-

terial, was tacked a piece of strong muslin. This was set in a sandy corner of the garden, and during the summer, cuttings of all kinds were placed in the soil beneath it. Sometimes the cuttings of shrubs were from sufficiently unripe wood, and all grew—sometimes the cuttings were too old and all failed, but take the season through, a wonderful amount of rooted stuff came out from under that little soap-box. Phloxes and Chrysanthemums, among herbaceous plants, were rooted by the dozens; and of even so uncertain a thing as "Bleeding Heart," some took root. This is something within the reach of every one, and we are sure that this, our first attempt in this way, gave us more real pleasure, than could the best propagating house.

New Varieties of Japan Iris.

It is stated elsewhere ("Notes from the Pines") that Mr. Thomas Hogg, who was the first to introduce *Iris Kämpferi*, has selected 20 of the finest varieties of this charming plant, to which he has given names, they having been heretofore known only by numbers. To avoid future confusion, it is desirable that these be placed on record, which we do in the interest of horticulture, and without the request, or even the knowledge of Mr. Hogg, giving, with the names, his brief descriptions, and also the numbers by which they have been designated:

1. *Ichibau*—Light reddish purple, pencilled with white; double; dwarf; medium early.
2. *Prof. Thuerber*—Purplish blue, mottled and spotted with white, fine yellow eye; double; early; first-class.
3. *Princess*—Lilac, finely pencilled with blue; double; dwarf; fine.
4. *Robert Buist*—Dark indigo blue, fine yellow eye; double; first-class.
5. *Mr. Buchanan*—Light indigo blue, fine yellow eye; double; large; extra fine.
6. *Emperor of Japan*—Maroon; first-class.
7. *Pearl*—Pure white; tall; early; first-class.
8. *Dainio*—Dark pink, pencilled with white; medium height; early.
9. *Fusiyama*—White, pencilled with purplish stripes, purple center; tall; early; first-class.
10. *Mr. Chotars*—Light blue, striped and mottled with white; tall; early.
11. *Minister Mori*—White, deeply laced with pink; early; first-class.
12. *Ieyas*—Purplish blue, solid color; tall; early.
13. *Murasaki*—Purple, wavy petals.
14. *Water Nymph*—White, deeply laced and shaded with lavender; tall; early; distinct.
15. *Diabertz*—Deep indigo blue; semi-double; dwarf; medium early; first-class.
16. *Imperial Standard*—Purplish pink, mottled with white; tall; early; first-class.
17. *Ontosama*—Light purple, slightly mottled with white; tall; very early; handsome.
18. *Empress of Japan*—Lavender, pencilled with white; tall; medium early; first-class.
19. *Perfection*—White, pencilled and mottled with purple; dwarf; medium early; fine.
20. *Virginalis*—Double white; extra fine.

The Burn-Heap.—Every garden of any considerable size has much rubbish to dispose of. It is not necessary to argue the value of a compost-heap, to which a large share of the refuse can be taken, to be converted into manure—at least not to any who have tested its value. But besides this, there is needed a burn-heap—and, we may add, what is not exactly a heap, but the reverse—a hollow, or place, to receive what belongs to neither the compost or burn-heap. As to this last, there will be on a large place some ravine to be filled, or low place to be graded, in which the small stones and other incombustible rubbish may be made useful. But there is much material that had better be burned; superannuated labels, pea-brush that has outlived its usefulness, the prunings of trees unavailable for firewood, and most especially those that have been cut away because of blight, the weeds that have been left alone (and the most careful of us have such) until seeds have begun to mature—these and many other things belong properly upon the burn-heap. The heap should, of course, be where no harm can come from it, and be fired from time to time, as fuel accumulates. We do not commend this as merely a method of getting rid of rubbish, but, well managed, it will give a supply of

ashes—a material so useful to the gardener, and so difficult to procure in thickly settled communities. If the ashes are gathered after each burning, one will be astonished at what a quantity may be thus obtained each season from material otherwise quite worthless. It is a trifling matter in the way of labor, but the valuable results are not to be despised.

THE HOUSEHOLD.

For other Household Items see "Basket" pages.

Home Topics.

Co-operation in Taking Homesteads.

Hard times have driven many persons to seek Western homesteads. Beautiful farms are to be had almost for nothing, except their actual settlement and cultivation. Yet these farms sometimes cost a great deal more than gets set down and footed up in the cash account. A little story has just been told me that illustrates this. It is about a young man who went from this State (Minnesota) further west, secured a homestead, built a small shanty, such as he could afford, furnishing it with the barest necessities for housekeeping, and then drove eighteen miles to the nearest railroad station, to meet his young wife. It was raining hard when they set out for "home," and the ox-team made slow work on the journey. Their clothes were soaked with rain when, late at night, they reached the lonely spot where they should have found a shelter. But the wind had blown away the light cabin, and the cooking-stove, and other heavy pieces of rude furniture were all that were left by the storm. They had nothing prepared to eat, and nothing dry to put on. Early the next morning they started for the nearest town, but the husband fainted before they reached it, and the sick young wife drove the oxen into the strange town,—to find help and friends; let us hope that they found needed aid, but I know nothing further of their story. Of course, this is an exceptional case, but it shows that every precaution should be taken to guard against exposure, lack of provisions, and undue fatigue. It is always a hazardous business for families to break up old associations, and go off to strike root in an entirely new place, far from neighbors, and entirely among strangers.—I am glad to see that better methods are taking the place of the old single-handed efforts at

Making Homes in the Wilderness.

There are colonization bureaus, which aid emigrants to settle in congenial groups, with some defence against the worst hardships of pioneer-life. The Catholic Church, in some cases, looks after members of its own flock seeking homes on the new lands, and settles them where they can peaceably worship God in their own way. In Minnesota there are several prosperous Catholic settlements, carefully planted and tended by the heads of the Church. The Odd Fellows settle people of their Order in pleasant companies, helping them to get a good start in the way of comfortable homes, with pleasant villages and adjacent farming population. Soldiers, seeking homesteads under the acts especially for their benefit, unite in associations, and send committees to find large tracts of good land yet unappropriated, where they may settle in companies and begin at once to enjoy the advantages of civilized life. This method is adopted by others than soldiers, and some of the most enlightened and prosperous settlements in the West have been started in this co-operative manner. Beginning in this way, with united enterprise and forethought, it becomes possible to carry out some of the excellent suggestions made by Col. Waring in his little book on "Village Improvements and Farm Villages." It seems to me, however, that in starting new villages, far from the great cities which furnish a ready market for farm produce in their vicinity, co-operation in machinery and work should be carried further than that book suggests. It should not be too exclusively a farm village, or a settlement of farmers. Of course, mills and factories, and a village population of mechanics and trades-

men would add greatly to the farmer's prosperity and to his social advantages. Enterprising men have founded colonies here and there, with more or less wise forethought for the good of the colonists, as well as for the building up of their own private fortunes. But why should not homesteaders themselves unite, getting their lands at homestead rates, and by associated effort in every way open to them, avoiding the worst evils of isolated pioneer life, and securing for themselves and families intelligent, industrious, and order-loving neighbors? This talk does not seem to me inappropriate for the household columns, since women and children are the worst sufferers from the loneliness and the discomforts of the usual pioneer life.

Maternity Alleviated.

"For lack of knowledge" not only do people die, but a very unnecessary amount of suffering is endured, and especially by the mothers of the human race. I have long wished to do something toward the prevention of this suffering, by telling other women a part of that which I know upon this subject. It falls to my lot to give private advice to a young wife, who suffered so severely at her first experience as a mother, that she looks forward with dread to its repetition. I think she need feel no physical dread whatever, if she is so situated as to carry out the latest approved methods. I confess I felt some prejudice against the new rules, fearing that what might contribute to the mother's ease and comfort, would prove detrimental to her child; but experience and observation have removed these prejudices. The experience was only partial, and was gained by following no rules but natural instinct. The very common desire for a change of diet, especially for acid fruits, is Nature's own voice, and should be obeyed. Apples were scarce and dear four years ago last spring, and I was ashamed to tell how many I sometimes ate at a meal (from five to ten small ones), but no other food was so delicious, and no meal gave me subsequent comfort without at least a single raw apple. A few months previous, I could hardly eat raw apples at all. Then grapes seemed the only food the stomach craved and accepted without nausea. As soon as the great event was over, and a little stranger looked to me for nourishment, the wish for fruit disappeared, and my oatmeal and graham gruel, seasoned with cream, became for a while the sweetest of delicacies. This experience was, for its ease and safety, a marvel to myself and to all who knew of it, and we were soon convinced that fruit diet and out-door exercise had caused the wonder. Since then we have heard of, and personally known, much more remarkable cases—equally beneficial to mother and child. A diet wholly of fruit is not recommended, but fruit should be very liberally used, and such food as contains much mineral matter, and tends to solidify the bones, should be avoided. The unseen growth goes on all the same, except that the bones remain in the cartilaginous state. It is easy to understand that this condition of the offspring saves the mother much pain, and a change to the ordinary diets immediately after promotes the child's full and healthy development. The graham and oatmeal, so useful to growing children, especially because they build up the bones, should be very sparingly used previous to confinement, and cream should be preferred to milk. The fruit diet has a tendency to keep the whole system in excellent condition. Vegetables are better than grain food at this time, beans being most objectionable, and peas and potatoes next. Rice, sago, and tapioca are recommended, and when meats are used, the flesh of young animals is preferred. Stimulants and spices should not be used. A good deal of gentle exercise is advisable, but severe labor and fatigue should be avoided. Household exercise, when not very confining, is excellent, but all the pure out-door air it possible to get, should be taken day and night. Walking is decidedly useful, and no false modesty should prevent a woman from going out freely for the exercise she so much needs. If she respects herself, she will have the respect of all decent people; but enlightened persons will only pity her ignorance, or silliness, if she shuts herself indoors for fear of observation. Of course, a modest

woman does not needlessly publish her sacred secret. The general rules of health, cleanliness, comfortable clothing, plenty of sleep, freedom from fatigue and excitement, regular meals, and none late in the afternoon, are all especially applicable at this time.

High Art and Woman's Dress.

Chief among artists in devising costumes, is the celebrated Worth, of Paris. But it seems that even he cannot do as he pleases, and is not responsible for all the absurdities of feminine attire. A number of American ladies, who were deeply interested in the subject, sent to Worth this question, "What costume can be devised that will be perfectly healthful, and at the same time beautiful?"—This is his astonishing reply: "I have to make the same answer to you that I have made to the women of Europe. The costume of the Persian women is the handsomest upon the face of the earth. It consists of a loose waist, short skirt and trousers, not too loose. I have made this costume beautifully, and hung it up in Paris, but the women will not wear it. I can do nothing more. They must suffer until they are willing to adopt it."

Now, who will dare to say that short skirts and trousers are absolutely and forever unbeautiful? That they are *unbecoming* to isolated women in public, at the present day, I am willing to admit, but I am quite positive that a dress that gives freedom to a woman's limbs will be entirely becoming when the mass of women are neither slaves nor pets, but mutual friends and helpers of men.

Who leads the fashions? We may say a word on that subject at another time. But there is a band of artists, poets, and others of their set over in London, a constantly increasing number, I am told, who refuse to be led about in costume by every fantastic whim that seizes upon the so-called leaders of fashion in Paris. So now we hear about the "Pre-Raphaelite style of dress." The aim is to have a thick waist—"thick like the Venus de Medici, thick like that far nobler Venus of Milo."

The artists declare that the small, tight-laced waists are decidedly unartistic and vulgar, and that the natural beauty of the female figure is lost by destroying its proper healthy proportions. The sleeves are very high on the shoulder, sometimes a little full, to fit the shoulders easily, for they insist that a woman should be able to move her arms, when dressed, as freely as when undressed. Isn't that a modern idea though? I remember well when it was common for women to unfasten their dress-waists if they had to rearrange their hair, their arms were so bound down by the arm-holes cut low on the shoulder, all for the sake of beauty, which *must* be regarded, however uncomfortable its victim. But of the freedom of the lower limbs, I hear nothing yet from the Pre-Raphaelites, except that the skirts must never be tied about the legs. We can wait, however, since the world does move; only let us quietly bear witness to the truth when it is proper to give our opinion, for public opinion is made up little by little.

Oat-meal Mush Improved.

Much better than the old way of stirring the oat-meal into boiling water, is the new way of cooking it in a farina kettle. If no farina kettle or steam-cooker is at hand, one may always be improvised in this way: Set a stone-jar or a tin-pail containing the food to be cooked, into a kettle of water (putting a couple of sticks under the jar, to keep it from direct contact with the bottom of the kettle),

over the fire, and keep the water boiling until the food is cooked. This method is best for cooking cracked wheat and hominy, and now I find it best for oat-meal also. [It is surprising to find one so generally well versed in the best methods of preparing farinaceous foods, proposing as *new* a method of preparing oat-meal and cracked wheat that we have practised almost daily, for years.—Ed.] Probably all of these materials are best cooked with part milk. Oat-meal is excellent when one cup of oatmeal is put into two cups of milk and two cups of water, and steamed for an hour and a half. Rice cooked by the same rule is very nice. No stirring is necessary, the salt being put in at discretion in the beginning of the cooking.

Sponge-Cake Cream-Pie.

One teaspoon of sugar, one teaspoon of flour well mixed with a level teaspoonful of baking-powder, three beaten eggs. Bake in a flat, square tin, and when cold, split open and spread with cream, prepared as follows: Whip a pint of sweet cream, until very smooth and stiff, sweeten and flavor to taste (those who like vanilla will prefer it in this case), and spread it stiff and cold upon the split sides of the cake, placing these two sides together again so that the cream does not appear, and the cake-pie looks like an ordinary cake. One can hardly find a more delicate and delicious dessert dish than this.

The Clothes-Moth.

Some housekeepers seem to have as much anxiety about moths as David Copperfield's aunt had about donkeys. Aunt Betsy was quite sure of her pet aversion, while many housekeepers accuse nearly everything that flies toward the lamp in the evening of being a "moth miller." Being on the lookout for some large creature, they accuse the innocent insects, and generally quite overlook the mischievous one, from its insignificant size. We every

CLOTHES MOTH—MILLER AND LARVÆ.

now and then get letters from those who have put away their store of woollens and furs for the season, which indicate a fear that something more should be done to insure their safety, or inquire about this or that moth preventive compound. Much of this anxiety would be removed, and much trouble in chasing and killing of insects which are quite harmless, so far as clothing goes, be saved, if housekeepers understood the appearance and the habits of their enemy. With this view we give an engraving of the common clothes-moth in its various stages of natural size and magnified. The form in which the insect is most popularly known as "moth," is seen enlarged at A, and of about the natural size on the cloth; it is really a caterpillar, shown naked and magnified at B, but it is rarely

seen, except in its case, or shelter, that it carries about with it. This case is made from minute bits of wool or soft hair which it fastens together with the finest possible silk, which it spins as needed. The insect feeds on the wool, which furnishes it both food and raiment, as it begins to build this case when first hatched from the egg, and goes on adding to it as its growth requires. It does not feed in one place, but travels about, cutting away the nap, and feeding here and there, often leaving a trail of its delicate silk, to mark its track. When it has completed its growth, the insect goes to rest in the chrysalis state, and in due time comes out a minute perfect moth; this, the dreaded moth-miller of the housekeeper, is shown at *C*. Its body is but a little over a fourth of an inch long, and its spread of wings only about half an inch; it is of a light buff color, and has a satiny lustre. So quiet is it in its flight, and so modest its appearance, that one who did not know the insect would not think it capable of so much mischief. In this state it flits about, looking for a dark place to lay its eggs, that will also afford abundant food for its young. The eggs being deposited, the life of the parent ends, and so soon as the young are hatched, they commence anew the work of destruction. These being the habits of the insect, it will be seen that clothing, etc., put away in such a manner that the mother insect can not reach the articles, in order to lay her eggs, will be safe. It is important to remember how small the insect is, and that it can pass through an opening not very much larger than a pin-hole. Articles, if proper care be used, may be made as secure *in paper* as in the most costly moth-proof trunk. Common boxes may be thoroughly covered with *paper*, outside and in, or a well-made box may be made secure by pasting strips of strong paper or muslin around the joints, after the cover is fastened down. Let the package be made moth-tight, and no camphor, cedar-chips, or other aromatic will be needed. When moths are once in a fabric, heat will destroy them; a heat less than that of boiling water (or 160°, it is said), will kill them. So will the vapor of pure benzine, such as is prepared for cleaning silks, etc. With proper precautions to keep them out, it will be unnecessary to resort to any measures of this kind. Before putting them away, the articles should be beaten, and carefully examined, so that no eggs or young moths may be put away with them. It is commonly supposed that June is the month in which special vigilance must be observed; this is an error, as the insects begin to fly in early May, and continue throughout the warm months. It is hardly necessary to add that all the perfect insects, or "moth-millers," that are met with, should be destroyed.

Household Notes and Queries.

Last month it was stated that, lacking just one, 40 housekeepers came to the help of their sister who wished for a recipe for the "Queen of Puddings." We had not then begun to hear from the "outer edge" of our immense circle, and can only say that of late the responses have come in such numbers that we have given up keeping count. It is certainly very pleasing, this readiness with which many others endeavor to aid one of their number; but what is more pleasing, are the good words which come with these responses. Several in furnishing the particular recipe asked for, add others voluntarily, and what we are almost as glad to have, some few ask questions to which they would like replies. All in good time—but now

"The Last shall be First," and we give place to the correspondent whose note has made the longest journey, Mrs. "L. M. S.," Whitman Co., Washington Terr. We would say to Mrs. S., and all others, no matter where they may be, that their contributions are none the less acceptable because they "live so far away." The *American Agriculturist* regards the whole American Continent as its field, and if others have the misfortune to live elsewhere, we claim them as a part of our great family, and extend to all the same welcome.... Our friend over "towards sundown," sends, besides the "Queen of Puddings," a recipe for

Apple Dumplings.—Use good sized, rather tart apples, pare, and remove the cores; envelope each separately in puff paste and tie it in a piece of cloth; boil or steam for one hour. Before serving, remove the cloths, cut a piece from each and put in some sugar and fresh butter; replace the piece of paste, and sprinkle with powdered sugar. If preferred, they may be served with liquid sauce or sweetened cream.... The same correspondent sends

Another Method, called "Apple Roll."—One lb. flour, one fourth lb. of butter; mix with sufficient water to make a not very stiff paste. Pare and slice rather thick, some tart apples. Roll out the paste as for pie-crust, and spread the sliced apples to cover it; sprinkle on a little flour, and roll up as tightly as possible without breaking the paste. Cook it in a steamer, or wrap in a cloth and boil for an hour. Serve by cutting across in thin slices, with sauce of butter and sugar.... Here comes a recipe from "Down East;" Mrs. "S. M. A.," of Conn., gives her method with

Baked Apple Dumplings.—Pare and core smooth apples of uniform size, and fill the cavity of each with sugar and a little cinnamon. Divide the paste into as many parts as there are apples; roll each piece out square, and enclose an apple in it, slightly wetting the edges to make them stick. Bake in shallow pans, and serve with hard sauce.

Rye Minute Pudding.—Heat milk to the boiling point, salt to taste, and stir in gradually rye-flour to make a thick mush. Cook about 15 minutes, and eat with sugar and cream. [This we know to be good, and it recalls pleasant recollections of early home life.—Ed.]

Evaporation.—A lady in Western N. Y. asks whether a liquid will evaporate more rapidly in an open vessel, or in a closed one, like a tea-kettle.—In an open one, most decidedly, as may be shown by taking two saucers of equal size, placing an equal quantity of water in each, and setting them on the back of the stove, or in other warm place. Now put a piece of stiff paper, piece of window-glass, or other material, over one saucer, so as to two-thirds cover it, and leave the other uncovered. The difference in time between the evaporation of the water in the two saucers will be very marked.... One asks if we know any preparation that will

Remove Hair from the Face without injury to the skin. We know of none, and do not think there is such a preparation. With considerable experience in such matters, having chemically examined them, all that we know of contain some form of *arsenic*. In the use of this, injury to the skin is the least danger; a greater one is that arsenic may be absorbed. We have seen many cases in which these have been used, and they leave the dark roots of the hair in strong contrast with the white skin, making the blemish, if such it be regarded, more conspicuous than before.... This brings to mind a most wicked adulteration recently discovered in Europe. *White arsenic* is a very heavy powder, and is so abundant in the refining of some metals, that the trouble is to get rid of it, hence it is a cheap substance, of which the supply is greater than the demand. Recent medicinal journals say it has been used to adulterate

Toilet Powder! Just think of it, one of the most deadly poisons known, used because of its cheapness, to add weight to an article applied solely to the delicate skins of women and children. Fearful and incurable skin diseases upon children to whom it had been applied to prevent chafing, led to the discovery. It is safe to discard all *French* toilet powder. Safe preparations are put up in this country, but each mother can make her own, because the best are only

Perfumed Starch.—Starch, made perfectly dry, and sifted through the finest sieve, may be used, or a few drops of any desired perfume may be mixed with it. Those who have lavender or other aromatic flowers can fold them in thin paper, and place these, with layers of starch, in a box, renewing the flowers every few days, until the starch has absorbed sufficient perfume. The starch will take up a little moisture from the flowers, and it is best to let it be exposed to the sun until quite dry, and then if at all lumpy, be sifted again.

BOYS & GIRLS' COLUMNS.

The Young Microscopist's Club.

Some of our correspondents write about things which are not quite microscopic, though they find our Microscope a great aid in examining them. For this reason, if I answer all those who write, I shall not always talk about really microscopic things. Here is a letter from "C. M. M.," Nahant, Mass., who writes that he has "made

A Very Curious Discovery

this morning—curious, at least, to me. * * * In rambling about the grounds I noticed that the grass appeared spotted with white. Examining it closely, I found it to be little clots of froth, or foam, looking much like spittle, and then I remembered hearing or reading of something called "Frog's Spittle," and thought that this might be it. There were great quantities of this froth, and I cut five shoots of grass with it attached, and took it to the house to examine more nearly. It was not thick nor glutinous, but thin, and likely to drop off, so I put it on a bit of paper, when, to my great surprise, seven little creatures commenced walking about. They were of different lengths, from a quarter to an eighth of an inch—a fat little body like that of our "Hay-makers" or Summer Locusts, with eyes and mouth very distinctly developed, and black, while the body was a greenish yellow, like the earliest leaves of the Sugar Maple. Now, I want to know what these little things are—how they came there—and what they will be eventually. Can you help me?"—The insect is one of a number which are called

Spittle Insects.

It is very difficult to get any definite information about our insects, unless they happen to be destructive to vegetation, in which case Harris in his work, or Riley in his various reports, is likely to have something to say about them. Others have written about insects, but their works, while they may contain the very information we seek, have such miserable indexes, that it is not easy to find what we want.... No doubt most of you understand, for I have often stated it, that insects generally make their growth in what is called the larval state—the caterpillar is the larva of the butterfly or moth, the maggot is the larva of some kind of fly, and so on. In their larval state, insects are often very slow moving and helpless, and there are many curious ways in which they hide from their enemies, especially the birds. Some insects have a way of hiding themselves in the larval state under the remains of their solid food—*i. e.*, completely cover themselves with a shield of their own dung. So these you found hide in the remains of their liquid food. They throw out a quantity of liquid within which they are able to form air bubbles, to make a sort of froth, which completely hides them, and under which they can feed and grow without much danger of being discovered by birds or other enemies. In England, this covering is called

Cuckoo Spit and Frog Spittle,

from the notion that the appearance is caused by birds or frogs. Any one who takes pains, like "C. M. M.," to examine the spittle, can learn the whole story. I do not know which particular insect my young friend found, but his likening it to the "Hay-maker" or "Summer Locust" shows that he was on the right track. In figure 1, is given the perfect insect of the most common of the English spittle insects, which presents a great variety of colors—*Phylloxera bifasciatus*. I have a book on insects by a very scientific American author, and some American species with this habit may be given in it, but as its author did not care to have us know whether he had either these or any other insect in his book, he has made no index; hence, his work is of no sort of value, and its nearly 400 pages may almost as well be blank paper, for all the use they are.... Here is another correspondent, (a young Miss, too,) at Orange, N. J., who has made

Fig. 1.

A Discovery of Another Kind.

Miss Cornelia was transplanting some plants from a window-box to the garden, when she "found these curi-

ous little seed-cups growing in the soil." No doubt of the garden, though she does not say so. She says: "I never before saw anything like them; if they are not of sufficient interest for some of your talks, would it be too much

trouble for you to drop me a postal, telling me the name of a book which would give me some information

Fig. 2.

about them?"—I often come across these little "seed cups," and they are very interesting things, but I do not know of any common work to which to refer Miss Cornelia, and will, for her benefit, and that of others, "talk" about them. Fig. 2 shows the appearance of the curious things. As Miss Cornelia's specimens were badly crushed, I give a drawing of some that I found in my own garden. This is of the natural size, and the affair looks much like a little nest with eggs in it, or, as Miss Cornelia has it, "little seed-cups." These "seed-cups" are really plants belonging to the great order of fungi—other forms of which you know, as toadstools or mushrooms. There are several that have the same general appearance as the one figured—a nest or cup, within which are rounded bodies, that have been likened to eggs, or to seeds. Their botanical names are *Nidularia* (little nest), *Crucibulum* (a crucible), and *Cyathus* (a cup). The little bodies within them that have been likened to eggs or seeds are cases holding the spores, or minute dust-like particles, which in these plants answer for seeds. It is said that some of these egg-like bodies in some fungi of this kind explode, and violently scatter their contents in all directions.

I had began to be glad that the questions ran less upon insects and more upon plants, and other objects, when I opened a long letter from "S. A. D.," Lowell, Mass., who is in trouble with his or her ivy.

Ivy Grown in the House

is very apt to be attacked by a scale louse, and that is evidently what is the matter in the case so carefully described by "S. A. D." If my correspondent—whether boy or girl, I have no clue—can command a piece of soft pine wood, or a not very stiff old tooth-brush, all the needed apparatus will be provided. Then two things more are needed:

A Desire and Patience.

By desire, I mean a real wish to be rid of the trouble, and patience will be needed to carry out the means. The microscope has done "S. A. D." one good service, as I learn from the letter that it has shown exactly what the trouble is—a scale louse that is for most of the time just fixed in one place—is always there if you want to find it, and also when you would prefer not to find it. When it has once fixed itself, it goes on providing for a new brood. Having provided "S. A. D." with the means of warfare—a pine stick or a brush, "he or she" is not the Yankee that I take "him or her" to be if these implements can not be put to good use. You have the scale lice there on the ivy; they will do much mischief if you let them alone. They do not move, but will be there tomorrow and next day, and the day after, but my advice is to attend to them *to-day*. Having a sharp pine stick, or a brush, you can put an end to the trouble; in other words, "kill 'em." I advise a soft pine stick or brush in preference to any other arms, as with these one can easily crush the lice and not injure the leaf or stem of the ivy. You may use soap-suds if you choose, with the brush, but the few times I have had occasion to kill them, I found the dry brush to answer.

The Doctor would like to say a few words to his correspondents, the "Boys and Girls." Some who write for youngsters, call them "My Dear Little Chicks," or, "My Darling Pets." I don't—I mean "Boys and Girls," for I think you will like it best. Well then, Boys and Girls, I would say to those of you who write me, that I do not *answer* puzzles. If you have anything to write about puzzles, send it to Aunt Sue, and if worthy, she will be glad to get it, and will treat it in the kindest manner. It is of no use to send puzzles to me, for I can't answer them, and wouldn't if I could. Several have written to ask me "if three cats will kill three rats in three minutes, how many somethings can be done in so many thingamys?" I am not sure that I have stated the thing rightly, but it makes no difference. If obliged to answer the problem, I should say if the cats were *my cats*, the number of the rats to be killed would be "lots." If it is of the least earthly interest to you to know any possible relation between cats, rats, and minutes, it is not to me—except to wish as many to be killed as possible—but I have no "minutes" to give to the problem. I only say "go ahead cats." The problem appeared, I think, in Aunt Sue's Department, I don't know how many months ago; and the strange thing is, that of late, several youngsters should send the problem, and ask me to answer it! Did you ever hear of Doctor Johnson's, the great dictionary man's, journey in Scotland? He was a very learned man, but was easily bothered over foolish little problems. The story goes that some one proposed to this learned man this problem: "If a herring and a half cost a penny and a half, how many herring can be bought for twelve pence?" It is said that the attempt to solve this problem so soured the temper of the venerable Doctor, that he never could write or speak pleasantly of Scotland thereafter. I am not intending to feel unpleasantly over such matters, but to say that they belong—everything of the problem or puzzle kind—to "Aunt Sue," and

should be sent to her, direct. That I not only know, but care nothing about such questions as this on rat-killing, only the more rats that are killed, the better I shall like it. When you ask me questions about the common things that surround you, when you wish to know anything that I can tell you about, I do not care how many letters you write me. But as everything in the way of puzzles is provided for—indeed you can not please good "Aunt Sue" so well in any other way, as by sending her a regular "pozer"—I must ask just once more all sensible youngsters to send all puzzle matters to her, and *not* to their friend,

THE DOCTOR.

Aunt Sue's Puzzle-Box.

SUNDAY ACROSTIC.

(Selected from names or words in the Bible. The first four lines indicate the initial and final letters.)

- They quailed upon the brink; behind them rang
The chariots thundering and the horsemen's clang;
Death seemed on every side, hut Hands Divine
Smoothed their safe passage o'er the obedient brine.
1. He, like a strong ass, crouching 'neath his load,
His brethren served, and in fair lands abode.
 2. "This place is God's," said Jacob; "here I set
This pillar, lest his warning I forget."
 3. Ah! fatal City! Where predestined war
Smote the rash monarch in his battle-car.
 4. He said,—and stretching to the Queen his hand—
"Ask what thou wilt, the half of all my land."
 5. When conflicts raged, and corpses strewed the plain,
He sniffed afar his banquet of the slain.
 6. Nor cold, nor hot, nor wholly vile, nor pure,
No strength to strive, no patience to endure.

MRS. OGILVY.

SQUARE WORD.

1. My first, a precious stone, we see.
2. My next an evergreen—a tree.
3. My third the name of lady fair.
4. A metal will complete the square.

ISOLA.

CHARADE.

My first all children like,
And older folks as well,
My second most all children like,
As older folks can tell.
Hayes and Wheeler were my whole
Before they were elected.
Tilden and Hendricks were my whole
Before they were rejected.

J. H. B.

HIDDEN TREES.

1. The boys made a large bon-fire.
2. They live up in Erie County.
3. O! a kite! a kite!
4. What a hovel my consins reside in!
5. It was a lonely place, dark and gloomy.
6. Oh! Mamma, please let Eddie go.
7. He may do as he pleases in the matter.
8. Look out for that bee, Charlie!

MARION.

SUBTRACTION AND ADDITION.

(Or taking the last syllable from the first word, and adding it to the next—e. g., 1. To clasp. 2. An ornament. 3. An epistle.—Solution—1. Embrace. 2. Bracelet. 3. Letter.)

1. Consideration. 2. Contrariwise. 3. A bird. 4. A room. 5. A slow movement. 6. To neglect. 7. A water-course. 8. A kitchen utensil. 9. A large rock. 10. Belonging to the skin.

TRY AGAIN.

EASY NUMERICAL ENIGMA.

- I am composed of 10 letters:
My 8, 4, 6, is to allow.
My 9, 8, 3, 10, is a river in Prussia.
My 5, 2, 3, is to deprive.
My 1, 7, 9, 8, is a dance.
My whole was a Confederate General.

CARRIE D. A.

SYNCOPEATIONS.

(Fill the second blank in each sentence with the same word, less one letter, as fills the first blank, without transposition—e. g., The — was only a — wide.—The road was only a *rod* wide.)

1. He made a — in the garden with a —.
2. She said it was her — to be —.
3. He told a long — about some — he drank.
4. They killed the bat in the mine, and his — was sprinkled over the —.
5. The boy tried to — an egg from the nest of the —.
6. Then cruelly tried to — the bird's —.
7. The — had a — on its head.
8. It made him — to drink the —, it was so strong.

JOHN W. WHEATLEY.

NUMERICAL ENIGMA.

- I am composed of 65 letters:
My 31, 22, 33, 29, 43, 15, 4, 39, 48, 61, 52, 33, 13, 41, 51, 42, 49, 50, 28, 55, 54, is the name of an American poet.
My 3, 35, 26, 13, 54, 8, 29, 7, 10, 17, 21, 14, is a Western city.
My 18, 2, 12, 9, 44, 59, 63, 35, 46, 6, 61, 32, 16, is "bell" in an ancient language.
My 24, 8, 5, 33, 23, is a title.
My 38, 20, 15, 25, 65, was the name of a wicked king who reigned nearly two thousand years ago.
My 53, 8, 37, 1, 56, 54, 30, 47, 27, 35, 61, 58, 11, 48, is a ragged fellow.
My 45, 62, 36, 40, 64, 54, is a near relative.
My 23, 60, 19, 58, 57, 34, is clay,—slate.
My whole is a well-known complet.

EHRICH.

Thanks for letters, puzzles, etc., to J. R. W. Hattie H. M., C. B. Riggs, J. J. Harrop, O. L. Rice, Evelyn K. N., Kendrie C. H., John W. Wheatley, Laura Irene B., and to others, whose inquiries I hope to be able to answer at some future time.

Correspondents will save time, if they will address their letters (to Aunt Sue) to Rowayton, Fairfield Co., Conn., from July to December of this year. But please remember that AUNT SUE is *not* Orange Judd Co.; the latter must be addressed at 245 Broadway, N. Y. City.

Aunt Sue's Chats.

J. H. B. sends some magic-squares, for the amusement of our puzzlers, wishing to have the figures, from 1 to 25, arranged in a square of 25 small squares, so that the columns, horizontal, perpendicular, and diagonal, shall each foot up to 65. Instead of giving the problem, I will show how any magic-square of uneven numbers (say 3 times 3, 5 times 5, 7 times 7, and so on) can be arranged correctly, every time. Let us take 5 times 5 for illustration. Begin with No. 1 in the square next below the center; go on downwards, diagonally to the right, until you reach the lowest line; then put the next figure in the top line of your square corresponding to the diagonal of another (supposed) square below. (See No. 3 in diagram.)

11		7		3	
4	12		8	16	4
17	5	13		9	17
10		1	14		10
	6		2	15	23

11	24	7	20	3
----	----	---	----	---

When you have written down No. 3, you will again be on an edge, so imagine another square (to the right) and go on diagonally, putting the numbers in your own square just where they would come in another square to the right; the 4 would come in the second horizontal column, first figure to the left, so put it there in your own square. (I trust that the diagram will help my reader to understand my description!) When any figure, already written, blocks you from pursuing your diagonal course, take the next square but one below your last figure. (See 5 and 6.) Go on in this way until you reach the lowest corner on the right, and then always put the next figure in the square next to the top one in the right column (see 15 and 16); then go on as before, and your last number should come on the square just one above the center. I have left some of the small squares blank, so that those

interested in the experiment may finish them for their own amusement. You may make a magic square containing 9,801 small squares, and fill them by the foregoing plan if you choose (?), and it will come out all right.

BETTINE.—I have received a letter from a young lady in Whitehall, Warrenton, Va., about crackers, who writes: "In the May Number of the *American Agriculturist* I see that 'BETTINE' did not succeed in making crackers by the recipe in the March Number, and as I know a very good one I send it. * * * To one pint of sifted flour add one tablespoonful of butter, and one of lard, with either sugar or salt to taste (we think salt the best, but some people prefer sweet things, so you can use sugar if you like); mix with milk-warm water, until the dough is rather stiffer than bread-dough; then heat it until bladders rise, then roll out very thin, and cut into any shape you like, and bake in a quick oven. The only trouble is about the beating; if too much is given, it makes the crackers heavy, and if not enough, they taste like dry paste; but about ten minutes is generally right. I hope 'BETTINE' will succeed, for it is provoking to fail in any cooking.—Yours truly, FLORENCE MILLER."

"**MOLLIE**" says she has "a lot of jet beads, and would like to know how to make a bead-hanging-basket, or anything else that would be pretty." She wants to know, also, what kind of ornaments are made with fish-seals, and how they are made. Who will tell her, how?

JENNIE R. W. wishes I would tell her how to solve diamond puzzles. I know of no better way than to give you a very easy one, and tell you the answer. 1. A consonant (sometimes a vowel). 2. A troublesome animal. 3. Something that every one drinks in some form. 4. A common beverage (much liked by old ladies). 5. A consonant. The central letters, horizontal and perpendicular, name a beverage.—Now you see there are 5 items, so the central words must have 5 letters. Take your slate and mark some little dots on it thus, . . . to show how many words and letters are required. The first item must be W or Y, . . . but as you are not sure, you leave that and try the next; that must be "rat." So put R A T in the place of the first line of three (horizontal) dots. Now you have on your slate: You think the third item may be "water," R A T but you are not sure; so skip that, and go . . . on to the fourth item. You feel sure . . . that that is "tea," so you write it down. . . . Now you are quite sure that the central perpendicular letters should be "water," . . . so you put it down. All you . . . W T E A have to do now, is to fill the . . . R A T horizontal line in the center . . . T E A with the missing letters, and you have your diamond complete. It is a very easy, simple R diamond; but it is very complete, because the perpendicular words are all the same as the horizontal.

One of our Largest Insects.

Several letters from boys and girls concerning one of our largest caterpillars will be here answered in "a

do not wonder that she called the caterpillar, for such it is, by such a hard name, for we know of no other among our insects, that looks so formidable as this. Its portrait, when full-grown, is given in figure 1, though it is sometimes nearly an inch longer than the engraving. A young girl is not to be blamed for calling it a "horrible horned creature," for it really looks as if it meant mischief, though it is quite harmless. This caterpillar is a great feeder, and lives mostly on walnut and hickory trees, though it will eat the persimmon and others, and

leave it until next June, when the moth will probably appear. After severe cold weather is over, it will be well to remove the box to the open air, and cover it with a piece of mosquito netting, or some such material, so that when the moths come out, they may not escape.

About Great Men—Bryant.

When I was a youngster, I had an excellent old friend, an Englishman, who was very fond of pictures, and who

Fig. 1.—THE ROYAL HORNED CATERPILLAR.

when feeding, as with other large caterpillars, its crunching and tearing of the leaves may be distinctly heard. When full-grown, it is of a green color, with a pale-blue band on each ring; the head and legs are orange-colored, as are the long spines, though their tips are black. Probably it is provided with these savage-looking horns, to frighten away the birds, but it can neither sting or prick, and may be safely handled. When it has completed its growth, the caterpillar goes into the ground and forms a chrysalis like figure 2; it remains in this state until the next season, when it comes out in June as a large and beautiful moth, like that in figure 3. This is known as the "Regal Moth," (the larva being the

Fig. 2.—CHRYSALIS OF FIGURE 1.

Royal Horned Caterpillar), and is one of the most beautiful of all our moths. Its general color is orange-red, the light spots on the fore-wings being yellow, and there are markings of dark-red and olive color. The name given by entomologists is *Cithæronia regalis*. The insect is never very abundant, but is found here and there all over the country; the first specimen of the moth we ever saw, though we had known the caterpillar, flew into a window of the building when we had our office, many years ago, on Park Row. It had probably perfected itself in City Hall Park, which was directly opposite. If any of you come across this savage-looking caterpillar, do not be afraid of it, even if it does shake itself

had many in the house I loved to visit. Among all his pictures, there were but two portraits—Washington and Wellington (perhaps he would have reversed the order of naming them). I once mentioned this peculiarity, the absence of other portraits, when he said that in his opinion these were the only two men who had ever lived whose portraits he cared to keep, and he added: "G—, I will never hang upon my walls the portrait of any living man."—How many times have I thought of this! A man so long as he lives is capable of doing something which may make us wish to turn his portrait to the wall. When he is dead, his account is closed, and we may then decide whether we wish to keep him in memory by having his portrait constantly before us. It may be a safe rule, that of my English friend, not to hang up the portraits of the living, but fortunately there are exceptions to this. There have been, and there are men—and women, too—whose portraits we may cherish, for the good that they have done, are doing, and are likely to do. We hear of great men, read what they have said, done, or written, and naturally wish to know what kind of men they are—how they look. This is a very natural desire, and a very proper one. I wonder how many school boys there are who have not spoken from their "speakers," or school girls who have not read from their "readers" that noble poem, beginning:

"To him who in the love of nature holds
Communion with her visible forms, she speaks
A various language;"

and ending with:

"By an unfaltering trust, approach thy grave
Like one that draws the drapery of his couch
About him, and lies down to pleasant dreams."

All of you know that this, and other familiar poems, is by Bryant, and naturally would like to know how Bryant looked, and what sort of a man was he, who could write poems that are familiar to young and old.

Nearly 25 years ago, when I first came to live in New York, my residence was in 22d Street. My business was far down-town, but unless it was very stormy, I, for the sake of the exercise, always walked down and up. Almost every spring morning I fell in with an old gentleman, with a long gray beard, flowing gray hair, and a countenance so strongly marked that I knew he must be "somebody." We were both bound down-town—and many a walking race we had. I was fresh from a prairie life, and a lively walker, but this old gentleman was more than a match for me, and often, though not always, out-walked

Fig. 1.—THE ROYAL MOTH (PERFECT INSECT OF FIGURE 1).

lump." We can not always reply to such inquiries as soon as they are received, as our engravings are planned well beforehand, and it does but little good to talk about an insect, unless we can give a picture of it, so that all hands may know the particular insect we are describing. Last year, "M. T. A.," of Washtenaw Co., Mich., wished to know about a "horrible horned creature," that was found upon the hickory trees in her neighborhood. We

from side to side; that is the way it protects itself from its enemies—by frightening them. If you wish to raise the perfect insect, provide a box of earth, in which stick leafy stems of the tree on which you find the caterpillar, keeping the earth fairly moist, but not too wet. Give them fresh leaves as needed, and when full grown the caterpillars will usually go into the earth provided for them; then you may put the box away in the cellar, and

me. All this happened without a word ever passing between us, but when we met, which was very often, there was a silent understanding that we were on a walking-match, and this continued until hot weather set in, when the old gentleman disappeared. That fall there was an exhibition of the New York Horticultural Society at which an address was to be given by William Cullen Bryant. I had a good lady friend who was, like myself,

WILLIAM CULLEN BRYANT.—TAKEN AT HIS COUNTRY HOME, AT CUMMINGTON, MASS.

an admirer of Mr. Bryant's poetry, and I invited her to go to the exhibition with me. Of course we both expected a treat, as such a poet, on such an occasion, could not fail to give us something poetical about flowers. We went, and found the room crowded. When the orator appeared—who should it be but the gray-bearded, gray-haired old gentleman with whom I had walked so many races all the spring months! This was a surprise, but when it came to the address, it was more than a surprise; it was a disappointment. We went expecting poetry, and got only pruning! A more matter of fact, and I will say instructive, lecture on pruning—pear-trees—I think it was, could not be given by one who never in his life read—much less wrote—a line of poetry. Some years later I became acquainted with Mr. Bryant, and found that he knew all about potatoes and pumpkins, even if he did write charming poetry about flowers. A number of portraits of Mr. Bryant have been published, most of them taken in profile, and very hard and

rugged. The one here given was drawn by an artist a few years ago, when Mr. Bryant was at his country home in Massachusetts. Mr. B. did not know that he was sitting for his portrait, and to my notion it gives him as he appeared in his home life better than any other. Why do I give you Mr. Bryant's portrait?—For several reasons.—first, because he is a writer of poems with which you are all familiar. Secondly, because he was one of the few men in active political life who never sought for or would accept office. Thirdly, as one who, though a strong writer in political controversy, was always a gentleman, and never used other than gentlemanly language. But these are qualities that will not interest youngsters. My main reason is that though he died at eighty-four, he was always a boy—a boy in activity, and a boy in the freshness of his spirits. He was born among the rocks, the hills, and woods, of Massachusetts, and though the greater part of his life was passed in a great city, and much of his thought was given to public affairs, his

true enjoyment was found among the rural scenes of his boyhood, and he will be remembered by his "Forest Hymn," his poem on "The Fringed Gentian," his lines to "A Water Fowl," his "June," his "Death of the Flowers," by boys and girls in generations to come, who will perhaps never know that he led an active city life and engaged in the political struggles of his day. I have no doubt that he would prefer to be thus remembered. He was a remarkable example of growing old gracefully. He would not have been what he was, he would not have been honored and esteemed as he everywhere was, had he not preserved his simple habits of country life, had he not cherished the memory of his early country home. The lessons of the woods and fields, the memory of the trees and flowers staid with him and kept his mind fresh and his heart pure all through a long and useful life. Every country boy who seeks a city career, may well study the example of William Cullen Bryant in his attachment to his early home.

THE DOCTOR.

TO COLON Address, Mrs. B. SMITH, P.O. Box 1954,
72 N. Fourth St., Philadelphia, Pa.

Pot Grown Strawberry Plants,

For immediate plantings, which will produce a full crop next June, a select list sent free to all applicants.

Turnip Seed Circular,

giving many hints of the great value of this crop and full directions for its cultivation. Also a list of **VEGETABLES** and **FLOWERS** SEEDS for sowing in August and September, mailed free.

Our **AUTUMN CATALOGUE OF DUTCH BULBOS ROOTS AND SMALL FRUITS,**

beautifully illustrated will be ready for distribution Sept. 1st. A copy will be mailed to all applicants enclosing Ten Cents; regular customers, supplied gratis. Address

B. K. BLISS & SONS, P. O. Box 5, 712

34 Barclay Street, New York.

Turnip Seeds, Grass Seeds,

SEED RYE, and SEED WHEAT, of all the leading kinds. **Special Prices for large lots.** Send for our Seed Catalogue. **R. H. ALLEN & CO.,** 189 & 191 Water St., New York.

TURNIPS! TURNIPS!

Our Early, White, Large Flat Turnip is the Farmers' Favorite Turnip. One Package of Seed, by mail 50c. Send for our Illustrated Circular of Seeds. Address **HAMBURG SEED FARM, Mount Airy, N. C.**

"GOLD MEDAL" STRAWBERRY PLANTS.

E. P. ROE offers for sale after the 1st of August, a large and superior stock of Strawberry Plants grown from beds producing berries that received the following premiums at the leading Horticultural Fairs, held at the great fruit centres at the East.

"The Horticultural Exhibition opened in Gilmore's Garden was thoroughly creditable. Mr. Roe was awarded the **GOLD MEDAL** for the best and largest collection of strawberries, and he also received the premium for ten quarts of as many distinct varieties. The second premium for the best ten varieties was also awarded to Mr. Roe."—*New York Times*, June 20th.

I also exhibited my strawberries on the 13th of June, at the Queens County Agricultural Exhibition, and received **1st Premium.** At the Newburgh Bay Horticultural Exhibition my strawberries were awarded the **first premium.** My strawberries have thus received from disinterested judges, most of whom are entire strangers to me, **THIRTY-ONE PREMIUMS** during the season just past.

A NEW FEATURE. Thousands of plants grown in small wooden boxes, and the boxes given away with the plants. One plant thus grown and shipped is worth half a dozen not potted or boxed. I can sell as cheaply as any one, furnishing the same quality of stock. Catalogue free to all applicants.

Address **E. P. ROE, Cornwall-on-the-Hudson, Orange Co., N. Y.**

Sharpless Strawberry.

What Ellwanger & Barry say of it:—"This variety (originating in Catawissa, Pa.) having fruited with us several seasons, we have no hesitation in recommending it as the Largest and Best Strawberry in cultivation. Send for Circular." **F. F. MERCEUR, Catawissa, Pa.**

NEW STRAWBERRY SHARPLESS. The largest, best flavored, and most productive berry ever produced. Berry raised with ordinary culture from plants set in Sept. 12 $\frac{1}{2}$ in. in circumference (weight 2 $\frac{1}{2}$ oz.), and on the same fruit stem four others from the size of a hickory-nut to that of a walnut. See sworn statement and recommendations in my circular, which is free to all sending their name on a postal card. Address **J. L. DILLON, Florist, Bloomsburg, Pa.**

CRESCENT SEEDLING STRAWBERRIES.

Pearlless Crescent Seedling stands without a rival. This is the third successive season this berry has produced fifteen thousand quarts per acre of fruit that readily sells in advance of Wilson. From two cents to eight, and always in demand. Single dozen plants sold in spring of '77, this season, has produced from one to two hundred quarts. In one case twenty-five plants produced four hundred quarts. Always so sure and get the genuine stock, as there are ten thousand spurious in circulation where there is one hundred genuine. **H. B. SMITH, West Haven, Ct.**

50,000 Transplanted Strawberry Plants.

Equal to Potted Plants, at one-fourth the cost; ready after Aug. 1st. Will yield full crop of fine fruit the following spring. Also a large stock of Peach and other Fruit Trees, Small Fruit Plants, &c. at low rates. Send for Circular giving Prices, Particulars, &c. **CHAS. BLACK & BRO., Village Nurseries, Hightstown, N. J.**

STRAWBERRY PLANTS.

For summer and fall setting. All the new and choice varieties, including President Lincoln, 11 inches around, Great American, Forest Rose, Beauty, Pioneer, Duchesse, Crescent Seedling, and many others. Circulars free. **G. H. & J. H. HALE, South Glastonbury, Conn.**

STRAWBERRY PLANTS for Summer and Fall Planting. Crescent Seedling, Cumberland Triumph, Forest Rose, Gt. American, Sharpless, &c. **SAMUEL C. DECOU, Moorestown, Burlington Co., N. J.**

GREAT AMERICAN STRAWBERRY Plants, Potted and G. common runners. Send for Circular, giving best method of culture, to **WM. L. RICHARDS, 22 Brill St., Newark, N. J.**

40 YEARS Among Small Fruits. Send for Catalogue of best varieties. **POMONA NURSERY, Chinnaminson, N. J.**

OF THE
STRAWBERRIES

Our Colored Plate, illustrating six of the best Strawberries, together with our method of culture by which a full crop can be obtained in TEN MONTHS from time of planting, mailed free to all applicants.

Peter Henderson & Co.
Seedsman and Market Gardeners,
35 Cortlandt Street, New York.

STRAWBERRIES. 6 inches—Largest—Best—Most Hardy and Productive. Plant this Fall and save a year. Great American, Monarch, Essex, Cumberland Triumph, Sharpless, very large, excellent, firm and productive. Greenheart, Pioneer, Cap. Jack, and others—**RASPBERRIES,** 3 inches, yield \$4.33 on 10 Acres. Send for Catalogues.

WM. PARRY, Chinnaminson, N. J.

STRAWBERRY PLANTS, in Pots, or out of Pots, for Summer or Fall planting. Price List free. **JOHN S. COLLINS, Moorestown, New Jersey.**

E. P. Roe's New Seedling Raspberry PRIDE OF THE HUDSON

More than sustains its high reputation. People come from far and near to see it, and all say it is the finest Raspberry they have ever seen. Send for circular. Address **E. P. ROE, Cornwall-on-the-Hudson, N. Y.**

THE NEW EARLY PEACHES.

Wildor, Saunders, Downing, Musser, Alexander, Amesen, and other varieties, fruited side by side. Price list and circular, giving our experience with the above this season, mailed upon application. **E. M. ENGLE & SON, Marietta, Pa.**

HYNES' SURPRISE.

The Earliest known Freestone Peach. Large, highly colored, very fragrant, a prolific bearer, and a good keeper. *Third year* of fruiting. Ripened in 1877 June 28th—in 1878 June 14th. Best of testimonials if desired. Buds \$2 per doz. Sent safely by mail to any part of the United States. P. O. Order or Registered Letter. **E. F. HYNES, West Plains, Howell Co., Mo.**

Peach and Pear Trees—a large stock. Other trees and plants in full supply. **New Brunswick (Nurseries) N. J. Edwin Allen.**

MY BULB AND PLANT CATALOGUE, containing descriptions of Hyacinths, Tulips, Lilies, and all Bulbs and Plant Seeds for Fall Planting in the Garden, and for Winter Flowers in the House—just published and sent free to all. Address **JAMES VICK, Rochester, N. Y.**

The Peerless Thresher and Cleaner—Clover Huller and Cleaner—Straw-Preserving Rye Threshers—Railway and Lever Powers—The Howland Feed Mill—Grain Fans and Corn Shellers. Our machines are guaranteed to work well, and have received the highest testimonials and cannot be excelled.

E. GILL & SON, Trenton Agricultural Works, Trenton, N. J.

The Hardest and Most Productive Variety of White Winter Wheat.**THE CLAWSON.**

I have a fine crop of over 30 acres of Clawson Wheat. Will clean it carefully for seed, and ship to any address for \$1.50 per bushel. New two bushel bags 25 cts. extra. Sample sent free by mail to all interested in the cultivation of wheat.

Red Brazilian and White French Varieties, cheapest hog food known. Send for Circular. **E. F. BROCKWAY, Ainsworth, Iowa.** Say you saw this in *Am. Agriculturist*.

Matthews' Garden Seed Drill,

Matthews' Hand Cultivator, Matthews' Drill and Cultivator combined, surpasses all others. Send for circular before you buy. Manufactured only by **EVERETT & SMALL, Boston, Mass.**

Experiments on Wheat and Grass.

A New and Simple Set of Fertilizers, Costing only \$5 per set, Adapted for Testing any Soil for Deficiency in the more Important Elements of Plant Food.

"COMPLETE MANURE SET,"

Designed for Those who Require a Set Requiring the Least Possible Care and Trouble in its Use.

This set consists of only four bags of uniform weight, (50 lbs. each), requiring no mixing or further preparation, to be applied on four alternate strips of Wheat, Grass, or other Crop. May be applied in Drill, Broadcast, or as a Top-dressing by hand or machine.

Bag A, 50 lbs., complete manure, containing the main ingredients in about the same proportion as, but in far more soluble and concentrated form than, stable manure.

The results from these four bags applied in four alternate strips will, during an average good growing season, indicate which one or more of the important ingredients Nitrogen, Phosphoric Acid, and Potash is deficient in the soil for growing the crop experimented upon. Full directions accompany each set. Any ordinary farm-hand can apply them. To each bag is attached a tag giving the number of pounds of each ingredient furnished, and the source from which obtained, with guaranteed composition. Bags A, B, C, and D, will be put up in a large bag as "Complete Manure Set."

Price, per set, delivered to cars or boat at New York, \$5. Price, with plaster omitted, requiring to be redneed in strength by mixing with a divider before use, \$4.50. Five sets (ready mixed), will be sent to one address in one shipment on receipt of \$22.50. The endorsement of this plan of experiments by nearly all the Agricultural Press, Agricultural Colleges, and Stations, as well as by many prominent agriculturists, has encouraged us to extend every facility in our power, including pamphlets and other descriptive matter calculated to insure its success.

Set A, including pamphlet on "Farm Experiments," written by Prof. W. O. Atwater, and blanks furnished as heretofore, at \$1. Any one or more single bags of Set A, and also of the extras (for full description and prices see *American Agriculturist* for April and May, 1878), furnished in connection with Complete Manure Set, at published prices. By combining with the Complete Manure Set either one of Bags I, II., and III., of Set A, the experiments may be adapted to any crop on almost any soil. Address,

THE MAPES FORMULA AND PERUVIAN GUANO CO.,
158 Front Street, N. Y.

Send for quotations of Fertilizers and Circulars. *Muriate of Potash* (\$9 p.e.), furnished by the single ton at \$35 per ton. For Fertilizers for Grain and Grass Crops see advertisement in *American Agriculturist*, July, inside front cover.

For Plantations and Oil-Mills. Used by Planters, the Oil-Mills in New Orleans and through the country. Send for Circulars and Judges Report. Pay for itself in a few weeks. D. KAHNWEILER, 120 Centre St., New York.

WHEAT.

A Great Instructive Experiment

will be made this Fall to prove whether or not the lack of BONE

in the soil is the cause of poor yields of Wheat and failure of Grass Crops. The application to wheat and grass of the Pure, Clean, Raw, Odorless, and Fine Ground Bone known as Premium Bone, has so clearly proved that Bone element is the great need, that we believe Farmers should make a wide extended experiment on a great variety of soils throughout the Union.

Out of what is the grain of wheat made? What are the proportion of its elements? What are they?—What is made out of Atmosphere and mineral or soil elements, in the following proportions:

Atmosphere (free to man).....	19,000 parts.
Phosphoric Acid (Bone element deficient in all soils showing exhaustion).....	498 "
Potash (seldom deficient except on soils under culture for a long period of years).....	237 "
Magnesia (enough in the soil for a long period of years).....	120 "
Soda (common salt element).....	91 "
Lime (in bone in its purest state).....	28 "
Silica (sand).....	16 "
Peroxide of Iron.....	7 "
Sulphuric Acid.....	3 "

20,000 parts.
19 parts of wheat is atmosphere. 1 part of wheat is mineral or soil element. $\frac{1}{2}$ of the mineral elements is Phosphoric Acid. Every ton of Premium Bone contains 560 lbs. Phosphoric Acid. Every bushel of wheat contains 3.5 of lb. of Phosphoric Acid. A ton of Premium Bone contains enough Phosphoric Acid to supply 933 bus. wheat, and a ton of Premium Bone being made from Raw Bones (not steamed or burned) supplies to wheat 100 lbs. Ammonia. Unless land has been cropped a very long time, there is no necessity for supplying anything outside of common manure, except Premium Bone. Farmers, write at once for terms for wheat seeding to

ERIE, PA.

THE GLOBE NAIL. THE BEST HORSE SHOE NAIL EVER MADE.

About ten years ago the **GLOBE NAIL COMPANY** of Boston, put on the market the first pointed, polished and finished Horse Shoe Nails ready for driving. Previous to that time all Horse Shoe Nails were pointed, and most of them made, by the shoers in their own shops at the rate of but six pounds per day.

The **Globe Nail** was at once found to be much cheaper and better than any then in use. It soon became so popular that all manufacturers of Horse Shoe Nails were compelled to make their Nails to resemble the **Globe.** For the last ten years it has been the model. Each year the Nail has been greatly improved in quality, and to such a point have we educated the shoers that now they will hardly use a nail unless it is absolutely perfect.

600 lbs. Finished Nails per day.

At the Centennial Exposition in Philadelphia, we were awarded the Medal and the following report, far stronger than that given upon any other Nail:

INTERNATIONAL EXHIBITION, 1876. U. S. CENTENNIAL COMMISSION.

[BUREAU OF AWARDS.]

PHILADELPHIA, June 22, 1876.

No. 239, **Globe Nail Co., Boston, Mass.**

Horse Shoe Nails, Pointed, Polished, and Finished. The uniformity in size, smoothness of finish, hardness and tenacity of the iron, closeness of fibre, and excellence of the head and point, the tensile strength of body, and riveting properties of these Nails, unite in making them of the very highest class of manufacture.

Recommended for an Award of Merit. DANIEL STEINMETZ, Phila., Chairman, J. D. TILDEN, Richmond, Va., CHARLES STAPLES, Portland, Me., G. L. REED, Clearfield, Pa., DAV. MCHARDY, Aberdeen, Scotland, T. DIEFENBACH, Germany.

Group Judges XV.

We annex a sample of the testimonials we receive daily from all parts of the country:

ST. LOUIS, Mo., June 8, 1877.

GLOBE NAIL CO., BOSTON, MASS.

Gentlemen: Find enclosed advertisement and postal card concerning your Nail. [Referring to a scurrilous advertisement and postal card, disparaging the **Globe Nail**, circulated by a rival manufacturer over the humble signature of "Humane Society for the Prevention of Cruelty to Animals." No Society bearing that title ever existed.] As I take a great interest in the prevention of cruelty to animals,—horses in particular,—I desire to say a few words in favor of **The Globe Nail.** Though I am not a very extensive Horse Shoer, yet I have used enough Nails of the different makes to speak knowingly. I have used the **Globe Nail** in my shop and on the race track for six years, on all classes of horses, from the heavy draft horse to the tender footed running horse; and I can safely say it has no superior in point of **Toughness, Shape, and Finish, if it has any equal.** I have used about fifteen hundred pounds of **Globe Nails** a year for the last six years, and in that time I have found four imperfect Nails, two of which I returned to you about two years ago and received in return four perfect ones, for which accept my thanks. If my men had no better sense than to drive those imperfect Nails in a horse's foot, I would not consider it the fault of the Nail if the horse was lamed. If horses would look more to the competency of their men and less to trying to get shoeing nails a few cents a pound cheaper, we would have fewer lame horses. I know for safety and durability, with a man who understands his business to drive them, your Nails can't be beat! I am willing to pay, without any suit, for all horses that are lamed in my shop by using the **Globe Nail.** As long as it is made as at present, I shall continue to use it, even if I could get other Nails for nothing. I consider it the safest Nail that was ever driven in a horse's foot.

Yours Very Respectfully, (Signed),

P. H. O'NEILL.

Horse Shoer, No. 1007 Broadway.

P. S.—I think I could get every boss in St. Louis to sign this if I thought it necessary.

P. H. O'N.

The best Horse is sure to win. SO CLEAR THE TRACK FOR THE

GLOBE NAIL CO.

Three Most Important Works.

Winter Greeneries at Home.

By REV. E. A. JOHNSON, D.D.

FINELY ILLUSTRATED.

12mo.

PRICE, POST-PAID, \$1.00.

This work differs from most other works on winter gardening in giving the results of actual practice. The title Winter Greeneries better expresses the scope of the work than would that of Window Gardening. All can make their rooms cheerful with green, while to successfully cultivate

many flowers requires more skill than the majority of people possess; still flowers are not omitted. A small but judicious selection of easily-procured and easily-managed plants is given, with which to enliven the greenery.

House Plans for Everybody.

By S. B. REED, Architect.

PROFUSELY ILLUSTRATED.

12mo.

PRICE, POST-PAID, \$1.50.

This is a valuable work which meets the wants of persons of moderate means, and we predict that it will prove one of the most popular architectural books ever issued. It gives a wide range of design from a dwelling costing \$250 up to \$8,000, and adapted to farm, village, and town residences. Nearly all of these plans have been tested by practical workings. They provide for heating, ventilation, etc., and give a large share of what are called Modern Improvements.

One feature of the work gives it a value over any similar publications of the kind that we have seen. It gives an estimate of the quantity of every article used in the construction, and the cost of each material at the time the building was erected, or the design made. Even if prices vary from time to time, one can, from these data, ascertain within a few dollars, the probable cost of constructing any one of the buildings here presented.

TALKS ON MANURES.

By JOSEPH HARRIS, M. S.,

Of Morston Farm, Rochester, New York. Author of "Walks and Talks on the Farm," "Talks on Farm Crops," "Harris on the Pig," etc.

12mo. PRICE, POST-PAID, \$1.50.

In the present work Mr. Harris continues the talking style which he has made entirely his own in agricultural teachings. He also continues our acquaintance with the "Deacon," the "Doctor," and the "Squire," and others of his neighbors who have been made, through the medium of these Talks, almost as well known as the author himself. While we have no lack of treatises upon artificial fertilizers, we know of no recent work in which the main stay of the farm—the manure made upon the farm—is treated at all satisfactorily or thoroughly. If this work should do nothing more than convince farmers throughout the country that the value of manure depends upon the quality of the food they feed, rather than upon the kind of animal that eats it, it will accomplish much.

But it does a great deal more than this; starting with the question,

"What Is Manure?"

it runs through in sufficient detail every source of manure on the farm, discussing the methods of making rich manure; the proper keeping and applying it, and especially the

Uses of Manure,

and the effects of different artificial fertilizers, as compared with farm-yard manure, upon different crops. In this the author makes free use of the remarkable series of experiments instituted years ago, and still continued, by Lawes and Gilbert, of Rothamsted, Eng. The

Remarkable Tables

In which the results of these experiments are given, are here for the first time made accessible to the American farmer. In fact, there is scarcely any point relating to fertilizing the soil, including the suitable manures for special crops, that is not treated, and while the teachings are founded upon the most elaborate scientific researches, they are so far divested of the technical language of science as to commend themselves to farmers as "practical" and inhospitable to science as the Deacon himself. The book should have a hearty welcome from every farmer, except the fortunate few who cultivate soils, the natural fertility of which is not yet exhausted.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from p. 287.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the "American Agriculturist," containing articles referred to in the "Basket" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.60 per volume.

Bitter Butter.—"Mrs. C.," Rockland Co., N. Y. The bitterness of the cream and the butter may occur from several causes. The cows may not be in perfectly good health; the feed may be in a condition to produce the flavor, or the weather may have this effect. A pinch of powdered saltpetre added to each pan of milk when it is put away, may prevent the bitter flavor.

Spots in Eggs.—"Barter." It is not unusual to find small reddish globules in Brahma eggs. We do not know the cause, and take no notice of it in our own case. When fowls are preparing to moult, the new feathers appear as small nodules in the skin. This is probably what you have observed in your fowls.

Cow Holding back her Milk.—"E. H.," Atlanta, Ga. When a cow holds back her milk, there is no way to compel her to let it down, unless her attention is attracted elsewhere. By the use of milking tubes we have been able to draw all the milk from a very obstinate cow. Probably from the absence of the usual handling she did not suspect she was being milked.

When to Sow Timothy.—"O. M. Y.," Monroe Co., W. Va. Where the winter is mild, it is safe to sow Timothy seed in the fall; where it is cold, there is danger of unfavorable exposure. Fall sowing is preferable to spring sowing, as the risks of the spring and summer are the greater. Yet spring sowing is very successful when the weather is favorable. When grass seed is sown alone, we would choose the spring rather than the fall. It is rarely that a good catch is missed when the ground is newly plowed, and the seed thoroughly well harrowed into the mellow soil in the spring. The earlier grass, or clover seed, is sown in the spring, the better.

Clogging of a Water-Pipe.—"J. L. M.," Wash'n Co., Pa. If it is possible to avoid spilling milk in the milk trough, it would be the best way to prevent the clogging of the pipe which carries off the waste. If this can not be avoided, we would suggest that the "fountain force pumps," made by Whitman, of Providence, R. I., be procured and used once a week for a few minutes to force water through the pipe in a rapid stream, by which sediment would be washed through. This force pump is very useful for clearing drain pipes of all kinds.

Value of Poultry in the United States.—"Subscriber," Attleboro, Mass. The statement that the value of the annual product of poultry in this country is greater than that of hay, corn, cotton, or wheat, is absurd. Any person who has a moderate acquaintance with what is going on about him, can make a pretty near estimate of the value of the poultry product. For instance, there are four million families in the country, and many of these do not keep fowls. Few persons produce over \$20 worth of eggs and poultry in a year; and if the average product were taken at \$20 for each family, the utmost total value of the yearly income from poultry would be only \$40,000,000.

Feeding Roots.—"G. H.," Schoharie Co., N. Y. Roots are fed either sliced or pulped. Machines are made for cutting large quantities. Smaller quantities may be chopped with a sharp spade, in a box.

Hemlock Boards for Granaries.—"F. H.," Bangor, Kans. It is held that hemlock boards are the best for granaries, because the timber is so full of splinters, that rats find difficulty in gnawing through it. A double-boarded floor is better than a single plank floor, because the joints are broken, and mice and rats, in gnawing through a joint of a double-boarded floor, are obliged to stop half way, when they could go right on through a plank.

Any of these three books will be sent post-paid on receipt of the price.

Orders from the trade will be supplied in succession as received.

ORANGE JUDD COMPANY, 245 Broadway, New York.

Keeping Unhusked Corn.—"T. K.," St. Jo., Mo. When corn is cribbed with the husks on, the husks gather dampness in wet weather, and if the corn is not perfectly dry when cribbed, it moulds. It is better to husk the corn before it is cribbed.

Preparation of Bones.—"C. A. J.," Davidson College, N. C. Making superphosphate of bones by using sulphuric acid, is only dangerous as a sharp axe is; care in handling is all that is necessary for safety. Bones can be reduced to plant-food more readily, however, by composting them with stable manure, or with muck. Even large whole bones will be reduced to a fine powder, and their constituent parts become plant-food, after six months in a properly prepared compost.

To Mend Iron Pipes Burst by Frost.—"D. & C.," Willowdale, Col. A burst pipe may be repaired by wrapping it very tightly with a strip of tarred canvass, or covering the injured part with a piece of sheet rubber, and then wrapping it firmly with copper wire or tarred cord.

Potato-Bugs Made Useful.—Aunt Sue passes her summer months on an island in Long Island Sound, where she follows fishing, shooting, and other out-door exercises that many women might, but do not. We let her tell her experience in her own way: "I have found a use for potato-bugs: Eureka! The other day a young lady said to me, 'Aunt Sue, let's go for black-fish.' 'Come along,' said I—'but have you got any fiddlers for bait?' 'Yes—a few.'—On our way, to the boat, we passed a potato-patch; and, of course, there sat the potato-bug. Said I, 'Fannie, I'm going to try some of these potato-bugs for bait.' 'Oh! do you believe the fish will touch the vile things?' 'We can but try.'—I fished with two hooks—baited one with a fiddler, the other with a P. B.—Up came a big flounder, 'Fannie! he chose the potato-bug!'—'No!'—'Yes!'—'...A glorious pull!'—Up came a big black-fish, and he elected the P. B. 'Tell the *American Agriculturist*,' said Fannie, 'I will,' I replied.—Hence these lines (these fish-lines).—Yours exultantly, AUNT SUE."

Fine Bone or Superphosphate.—"H. W.," Lime Mountain, Pa. If the fine bone-flour is used, there is no need to add sulphuric acid, the plant-food of the bone being sufficiently available without reduction by the acid, for light soils. And composting with stable manure for 3 months, will fit it for any land.

How to Accustom Colts to the Halter.—A correspondent from Delaware gives the following directions for breaking colts to the halter: Put a head-halter on the colt. Never halter it around the neck, because when frightened it is apt to pull the neck out of place, which has happened in many instances. Secure the halter to the manger; allow no more length of halter than will permit the colt to lie down, lest it should become entangled. Halter it about half an hour in the daytime; increase the time upon second and third days, then let it remain haltered all night; go and see it a few times before retiring. By this method I accustomed one to the halter at six months old with success.

Removal of a Ram's Horn.—"P. F. L.," Tuolumne Co., Cal. If the horn is about to destroy the ram's eye, the end of it must certainly be removed. If cut off with a fine saw 2 or 3 inches from the head, it is probable that the ram will suffer no injury nor any inconvenience. If the horn should be hollow there, a horn plug should be inserted, cut off level, and the end touched with a hot iron, which will fasten the plug in its place securely to the horn.

Old Pasture—Irrregularity in Milk.—"M.," Hamburg, N. J. To renovate the apparently exhausted pasture, you should plow under the "five-finger, running blackberries, smach, etc.," with a strong team. Then sow rye—with which you might use some of the commercial fertilizers—plowing it under just before it would be ripe enough to harvest. Then the land would probably be in good condition to raise any crop by use of manure.—The falling off in quantity of milk, in the morning, twice a week, may be due to the cow's being milked by other parties, or possibly from failure to get water.

Wool-tying Box.—"M. M. C.," Davenport, Iowa. Descriptions and illustrations of wool-tying boxes were given in May, 1872, and June, 1877.

Blue Devils is the popular name for a very handsome weed, of which the botanical name is *Echium vulgare*. It is very abundant in Virginia and the Middle States, and has gradually worked its way northward. In a recent visit to Orange Co., N. Y., we saw several places where it had become well established. It is scarcely less to be dreaded than the Canada Thistle, and we warn all those, upon whose farms it has obtained a

foot-hold, to prevent its spread. Otherwise they will be looking out for new farms, where this pest is not known. "Blue Devils," *Echium vulgare*, "Canada Thistle," *Cirsium arvense*, "Toad-flax," *Linaria vulgare*, and "Horse-Nettle," *Solanum Carolinense*, are the weeds that are most to be dreaded by farmers of the Northern and Middle States. The farmer or the weed will have possession of the soil. There can be no compromise; it must be a successful fight, or a surrender.

Railroads in the United States.—Interesting and suggestive figures are given in "Poor's Railroad Manual" for 1878. At the close of 1877 there were in operation 74,112 miles—about enough to make three continuous lines around the world. Six years previous, there were only 44,614 miles, an increase of nearly 30,000 miles within the present decade. (We remember riding on one of the first railroads, 20 miles long, consisting of flat strips of iron, like wagon-tire, spiked on the top side of scantling string pieces). What a saving of wagons and horse-flesh, these 74,112 miles of railway effect!... The cost of these railways is set down at \$4,568,597,248. The total value of the farm lands in the United States, by census of 1870, was \$9,262,803,861. Thus, then, the cost of the railroads would buy half of all the farms in the country. Take away these railroads and the value of the farms would doubtless be diminished fully one-half or more.... Those jealous of the railroads, should note that while the value of farms and the property has been doubled and quadrupled by the railroads, those who have furnished the money to build the roads get a poor return. The profits of running the railroads during 1877 were \$170,976,697. This is only a little over 3½ per cent on the money invested in them. In 13 States the railroads paid no dividends (viz., Col., Fla., Iowa, La., Minn., Miss., Mo., Neb., Oregon, Tex., and Vt.)

New Process Flour.—"A. G. A.," Florence, Mass. A few months ago the so-called new process of grinding wheat was described in the *American Agriculturist* at length. It is simply a double grinding; the first separates the bran, the stones being set as wide apart as possible, and breaks the kernel into coarse fragments. These are sifted from the bran and reground. By this process the second layer of the grain, is all retained in the flour, to the great improvement of its quality. In ordinary grinding, this second shell goes out with the bran as middlings, and is lost to the flour.

Making Cheese.—"Young Housekeeper," Harrington, Conn. In the *American Agriculturist* for Sept., 1875, is an article fully describing two methods of making cheese, with accurate measures of the quantity of rennet to be used, the mode of preparing it, and how to handle the milk for cheeses of particular size.

Bone-Ash, Bone-Black, or Bone.—"R. R.," Baltimore Co., Md. Bone-ash has no organic matter, but often contains as high as 40 per cent of phosphoric acid. Bone-black contains no nitrogen, but has about 30 per cent of phosphoric acid. Of the two, bone-ash evidently possesses the highest value; either, to be of much use, should be treated with acid, or better for the farmer, composted with stable-manure or muck for three to six months. Pure bone contains from 2 to 4 per cent of nitrogen, and about 20 per cent of phosphoric acid. This is perhaps the best form of the three for farm use, on account of the nitrogen, and because it is readily decomposed in a light soil, or in a compost heap.

Value of Gas Lime.—"A. J. H.," Crawford Co., Pa. Gas lime, when fresh, is positively injurious to vegetation. After exposure to the air for a time, it is useful as a fertilizer, but bears no comparison with barnyard manure in this respect. After gas lime has remained exposed for a year, 50 bushels to the acre may be used upon heavy land prepared for fall grain and grass, or for corn.

Drainage of a Springy Meadow.—"P.," Ridgway, Iowa. A ditch, as a matter of course, should have its size fixed with reference to the quantity of water to be carried off. It is better to make it too large than too small. Its depth will depend upon the lay of the land, the fall required, etc. A width of 4 feet may be necessary in soft soil, the sides to slope to 2 feet wide at the bottom. With a good fall this would carry off a large quantity of water flowing only one inch deep. In throwing out the earth, it is best to have it all on one side of the ditch, as it can then be removed easily, and if the ditch needs widening there will be no earth to move twice.

Butter Factories.—"D. McN.," New Brunswick. A butter factory for 100 cows could not be carried on so profitably as one for 600. The cost of the ground, building, churns, labor, fuel, water, and many other things for the small factory, would be equal, or nearly so, as those for the larger one, while the returns would be but one-sixth. Still, where the number of cows

is limited, it will pay better to churn for 100 in one factory than in 10 or 12 farm houses. Plans and estimates for creameries would, perhaps, be furnished for a reasonable compensation by O. S. Bliss, Secretary of Vermont Dairywomen's Association, Georgia, Vt.

Typhoid Pneumonia.—"P. K. S.," Durham, Me. The symptoms which occur in a case of this disease are a changeable pulse, eyes dull and prominent, cold horns, excrement dark, bowels sometimes constipated, and at other times loose; loss of appetite, dullness and disinclination to move, and a dry, hot muzzle. When opened after death the lungs are found dark in color, and the stomach and intestines are dark-green, or lead-color, with the skin or membranes so nearly decomposed as to loosen and become detached at a slight touch. This disease is very virulent and difficult of cure.

Pruning Evergreen Hedges.—"S. G. H.," It all depends upon the condition of the hedge. If the hedge is young, and it is desired to promote its growth, a trimming of superfluous shoots in October will be all that is needed. On the other hand, if the hedge is well established, and it is necessary to check its luxuriance, new shoots may be cut back early in June, in addition to the October pruning to preserve the proper shape.

Fourteen Thousand New Books. written by Ten Thousand different Authors, are reported to have been published in Germany during 1877, of which 2,400,000 copies were printed, or an average of only 171 copies of each new book, and only one copy of the whole number for each 20 inhabitants. Statistics show that only one out of each 50 of the people bought one of these new books. About half of the 2,400,000 copies printed were sold outside of Germany. On an average, then, these German Authors had only 86 readers among their countrymen. There were, however, some six million Almanacs printed, and these are usually larger than with us.

The "White Grub" and Strawberries.—Here comes a most pitiful letter from Pietou, Nova Scotia, to the effect that if the ravages of the "Grub" can not be stayed, they must give up the culture of the strawberry. It is the same sad story that we get every year from various quarters. "The first intimation that we have of the mischief is by the plant suddenly wilting, and if taken up at once he (the grub) is found at the roots." Then, of course, follows a request for a remedy. Our White Grub is the counterpart of the *Hanneton*, such a pest to cultivation in France, and for the destruction of which the Government some years offered a prize, which has not yet been awarded. Our "White Grub" is the larval state of the common "May Beetle" (*Lechnosterna fuscata*), which bounces about our rooms in the evenings of May and June. The grubs are usually three years in the ground before they come out in the perfect or beetle form, and it is probable that most of their mischief is done in their last year, when they destroy everything that comes in their way—even nursery trees as large as one's finger. They have many natural enemies, but enough survive these to make them in some places a calamity. All that our Pietou friend can do is, when a strawberry plant wilts, dig for and find the grub, and prevent that one from further mischief or increase. When the perfect insects, or May-bugs, are abundant, they generally collect on fruit or other trees, from which they may be shaken in early morning, caught on cloths, and destroyed. If the grubs are found abundant in the soil in plowing or spading, it will pay to employ children to pick them up as they are exposed by turning the soil. Thus far, these mechanical means are the only ones known for the reduction of this most serious pest.

Protection for Trace-chains.—"T. P. B.," Evansville, Ind., describes a little "Yankee notion" that is used "out West" to keep the trace-chains from rubbing the shoulders, sides, and legs of horses when plowing, harrowing, or to the wagon.—"We get worn-out gun-hose; about 1-inch hose is the proper size to take in a trace-chain. It costs nothing, as our city friends are always glad to get rid of leaky hose. We cut this hose in pieces to fit; one from the hame to the back-band, another piece from the back-band to within a foot of the single-tree, taking four pieces to rig each horse. It works like a charm. The horse will not have a hair amiss if worked with chains thus enclosed."

His Compost Heap.—A correspondent in Ontario refers to the article in June last headed "A Warning to Every Housekeeper," which refers to the common neglect of privies, and asks if he is to apprehend danger from his compost heap, in which he prepares manure for his garden. The use of dry earth, as suggested in that article, will prove equally efficacious with the compost heap. If, after turning the heap, the surface is covered with a few inches of dry earth—sufficient to prevent the escape of unpleasant odors—we do not think that any gases will arise from it detrimental to the health of his household.

When a Cow Comes in Season.—"J. F. H.," Louisville, Mo. As milk is a more valuable product than the calf, the object should be to make the season of milking as long as possible. A cow will generally come into breeding condition in three months after calving, or, if well fed, sometimes in two months. By keeping the cow from breeding for three months we have about ten months of milking, and can give the cow two months rest. In general, this plan is the most desirable.

Cotswold Sheep and Angora Goats.—"R. D.," Pittsburg, Pa. It is a mistake that some people make to suppose that the Orange Judd Co., or the editors of the *American Agriculturist*, deal in, or sell seeds or live stock of any kind. No persons officially connected with the *American Agriculturist* has anything to sell excepting their own farm produce in the ordinary way in the markets. The advertising columns of this Journal contain in the course of a year the names of persons from whom almost anything can be purchased—from a copper-toed shoe or a watch-key up to steam-engines, farms, live-stock of all kinds, and other things large and small, too numerous to mention.

Hard Lump in a Teat.—"E. C. W.," Montcalm Co., Mich. To treat a hard swelling at the base of a cow's teat, apply twice a day about a teaspoonful of a mixture of Glycerine, 7 parts; Iodide of Potassium, 1 part. If the iodide does not readily dissolve, add a little water to the mixture. A small quantity of this should be poured into the palm of the hand, and rubbed about the swollen part, using gentle pressure and kneading.

Salt for Animals.—"H. M. J.," Milwaukee, Wis. It is better to give horses, sheep, and cows, a daily allowance of salt, by placing a supply where they can themselves procure what they want. Otherwise they may be supplied once a week on a certain day and at a regular hour. Saturday evening is a good time for this.

Dysentery in Pigs.—"J. B. H.," Mount Holly, N. J. This disease is frequently caused by close confinement in warm weather. When swine are confined in pens, they should be kept clean, cool, and thickly bedded with dry earth. Some green food should be provided daily. To treat the scouring, give a teaspoonful of linseed oil to an old pig, or a tablespoonful to a young one, and repeat the second day. Then give, in some sweet milk, the crushed fragments of a pound of flour boiled dry in a cloth for three hours.

When a Cow's Milk is Good.—"C. P.," Milk is fit for table use the fifth day after calving. Many people do not object to use the first milk, which coagulates readily by heat, as a material for custard.

A New Way to Use Paris Green.—"J. B.," uses this pest poison, by mixing two ounces of Paris Green with a half pint of flour in just water enough to wet the mass; then he fills the pail with water, thoroughly stirs it, and says the mixed flour and green stays mixed, and washes from the potato-vines with difficulty. [We should say one ounce to a pail of water.—ED.]

Railroad Conventions are frequently reported here and there. We suggest that a pretty general one might be profitably held "on or along" the Long Island Railroad. Those attending might then learn some of the secrets of the success of the present management; how they contrive to please everybody—almost; to reduce the number of trains, and the expenses, and yet run just the trains everybody seems to want, when and where they are wanted, and as they are wanted. The result is, general satisfaction, and a much larger business than ever before. One of the secrets of success we hinted at some months ago; viz, the managers considered the interests of the road and its patrons, farmers included, as being *mutual*, and they had the necessary skill, experience, and *common sense* to carry out this idea.

Driving Posts by Machinery.—"J. N. M.," To drive posts by means of a small portable pile-driver, can hardly pay. It is too much like using a trip-hammer to crack nuts. The power of one man is sufficient to drive any fence-post, and if a pile-driver is used there must be three men employed, and a horse or two. There would be a loss of at least of one man's labor, without counting the cost of the machinery.

The Medical Register of New York, Connecticut, and New Jersey, William T. White, M. D., Editor, is published under the supervision of the New York Medico-Historical Society. As we have a large number of physicians among our readers, we call their attention to this work as one not only likely to be useful to them, but as an example of what should be done for every State in the Union. This work not only gives the name of every physician in the States mentioned, but the college from which he graduated, the societies of which he is a

member, etc. In New York City we have not only the address of every regular physician, but a directory of streets giving the name of every doctor in each locality. We find the work so full of information of various kinds, that we can commend it to the profession generally.

Plaster Upon Clover.—"C. J. B.," Rensselaer, Ind. Plaster may be usefully applied upon the young clover as soon as the grain is cleared from the field. There is no other time in the life of a plant when a fertilizer can be more usefully given than when it is young and struggling for existence. 100 pounds of plaster per acre is a proper quantity to use. The yield of seed is improved by it as well as the growth of the fodder.

A Georgia Flea Trap.—"The Savannah News" reports the following as from another paper, name not given: A gentleman placed a plate of molasses under a house where the fleas loved to congregate, drove a little stake on each side, and fastened a sheet of writing paper to the stakes, so that it stood vertically (or on its edge) over the plate. The insects, true to their instinct to make for anything white, began to jump against the paper, and to slip down into the molasses. The scheme was a success, and thinned out the marauders rapidly. The plan sounds plausible, and may be worth trying. We can't vouch for the instinctive attraction to white.

Butter Coloring.—"R.," Auburn, Cal. Several preparations for coloring butter have been offered in our advertising columns during the past year. These are probably preparations of *Annatto*, the colored pulp that surrounds the seeds of a South American plant, or *Annattoine*, the coloring principle separated from this pulp. Here is one formula for preparing it: Dissolve one pound of best *potash* and half a pound of *soda* in ten quarts of water, pouring off all the clear solution possible. Put one pound of *Annattoine* in two gallons of water; let it stand in a cool place for two days, with occasional stirring. Mix the two liquids together, stirring occasionally, for two days, then pour off the clear portion and keep in a stone jar, or if in glass bottles, put them in a dark place. At churning stir in a tablespoonful of the liquid to each gallon of cream, using more or less according to the depth of color required.

Conn. Oleomargarine Law.—"The last Connecticut Legislature enacted that: "No person shall offer for sale or have in his possession for sale an article known to commerce as 'Oleomargarine,' being a substance manufactured from suet or tallow and resembling butter, without having the word 'Oleomargarine' plainly stamped or written on the enclosure. All persons guilty of violating the preceding section, shall be fined the sum of fifty dollars for each offence, one-half to him who shall prosecute, and one-half to the town where the offence shall be committed."

Paris Green.—"F. W. M.," Hudson, N. Y. It is no new fact, that when Paris green is brought in contact with a cut or abrasion of the skin, the person may get poisoned. The attention of the readers of the *American Agriculturist* has been frequently called to this, and proper warning given again and again. Paris green is dangerous, as a sharp axe is, and needs to be handled with care; but it should no more be tabooed on this account than the axe.

Yield of a Cross-Bred Cow.—"A correspondent from Cumberland, Md., sends a statement to the effect that a cross-bred Jersey and Shorthorn cow, owned by a resident of Frostburg, in his vicinity, gives a daily yield of 24 quarts of milk, from which 18 pounds of butter has been made in seven days. The cow is five years old, and has been fed on pasture alone.

Kerosene for Hen Lice.—"J. B.," Naugatuck, Ct. While the kerosene will destroy vermin by the thousand, its effects are not lasting, as it soon evaporates. To be effectual it should be applied to the roosts and wood-work frequently, say once a week. The red color of some of the lice is due to the blood sucked by them from the fowls, as mosquitoes become red after dining on human blood.

To get rid of Poultry Vermin.—"L. A. G.," La Salle, N. Y. To cleanse a hen-house or a barn, of lice, you may wash the inside in all infested parts with a strong solution of carbolic acid; then close the building for a day, and afterwards whitewash the interior, repeating the same two or three times a year. With such treatment, and keeping the coops free from droppings, no trouble will be experienced. Lice on laying fowls can be destroyed by the use of carbolic nest eggs.

Cramps in Turkeys.—"G. G.," Greenville, Ill. Your young turkeys, which, when two weeks old, had their "legs all drawn up and toes twisted out of shape," had the cramps or rheumatism, probably caused by close in and in-breeding, or confinement in damp quar-

ters, or from being reared by hens. It is held by some that as a hen always broods in the same place at night, the young turkeys thus take injury, perhaps generate some poison, which results in the disease. On the first appearance of the cramps, bathe the parts in hot mustard water, by letting the chicks stand in it; feed two grains of bromide of potash in soft food daily, and move the brooding coop each day. (A hen turkey left to herself will not brood twice in the same place.) I. K. FELCH.

Chicken Cholera.—"P. S.," Fort Erie. Chickens which have a diarrhoea, voiding sulphur-colored droppings, and mope for a day or two and then die, probably have the cholera. Of the many reported "specifics" for this disease, very few, if any, will effect a cure. To prevent the scourge, feed a tablespoonful of sulphur to 25 fowls, twice a week in their food; and keep crushed charcoal where the poultry can eat it when they like.

Canada Thistle.—"J. L. M.," "J. D.," and others. Cut now, before it goes to seed, and burn—that will prevent further seeding. There is no special application to kill this or any other weed, that will not injure useful plants. Canada Thistle usually appears in a patch, in the field or on the roadside. It is rather late; still, go at it, mow and burn. If it springs up after the mowing, mow again, and do this as often as it starts this season. Next spring, look for it, mow and keep mowing; whenever it is six inches high, cut it. By keeping at it, you can subdue it, but if you have not the needed persistence, it will get the better of you. Where the thistle appears in small patches, we have known it to be subdued by making these the regular places for salting sheep.

Farm Accounts.—"Young Farmer." It is as necessary for a farmer to keep accounts as for any other business man. Not one farmer in a hundred, or perhaps in a thousand, knows how he stands with the world, how much he owes, how much his crops cost him, which of them are profitable, which grown at a loss, how much they yield, or what a proper day's work of a man is. Few can tell how much grain a man can, or should thrash in a day, or decide any such common question; and the majority of old farmers have spent their lives in guessing, or perhaps not even caring to do so much as that. To succeed fully in any undertaking, one must keep accounts. To do this is very easy. Get a small book, and have one page for every crop and every kind of stock. Have another in which every day record all that is done, every purchase, every sale, the quantity of feed used, cost of work done in each field, and the value of each crop. From this book the items are carried to the separate accounts in the other book to which each belongs, and in each account the total at the end of the year will show the charges and credits for each field, for each kind of stock, and for each crop. There is no need to keep these accounts in any complicated way: the more simple and plain they are the better.

Composting Dead Animals.—"T. B. P.," Goldsboro, N. C. The best method of utilizing the carcasses of dead animals is to put them in a compost heap of stable-manure or muck, either whole or cut in pieces. The heap should be wet from time to time to forward the decomposition. There need be no offensive smells if there is sufficient muck, or if the heap, when manure is used, is well covered with earth. In six months at farthest, the carcass will be thoroughly decomposed, and converted into an excellent fertilizer.

Poultry in Stables.—"Reader." It is best to avoid keeping poultry in or near stables, because they are generally neglected, and become infested with vermin, which get upon the cows or horses. But it is only for this reason, and if the fowls are kept clean, there need be no such objection. Poultry houses may be kept perfectly free from vermin by painting or whitewashing the interior, making the floor of cement, and keeping it cleanly swept and sanded at least once a week.

Fine Asparagus.—"The winners of the prizes for Asparagus at the Spring Exhibition at Mueola, Queens County, N. Y. Fair, were Valentine Frost, Locust Valley, and George H. Townsend, Glenhead, both of Long Island. When the exhibition was over, they sent us their exhibits, and though we may have seen larger single bunches, we do not think that we have before seen so much large and really fine asparagus together. Both these prize winners attribute their success to the use of "Mapes' Special Fertilizer for Asparagus," which was the only fertilizer used upon the crop.

James Fleming, well known as a gardener, and later as a seedsman, died on July 10th at New Canaan, Conn., at the age of 45. Mr. F. was a native of Ayrshire, Scotland, and came to this country while quite a young man; he had charge of some of the finest private collections in the country, and in the capacity of gardener, as well as that of seedsman, he made a large circle of friends.

Gold Detecting.—"A. W. R.," Placer Co., Cal., asks, "what acid is used in determining the presence of gold in minerals or soil?"—If gold is in its *native* state, the form in which it is frequently found, the grains will not be brittle, but will flatten if hammered; they will not dissolve in any ordinary acid, but only in a mixture of nitric and muriatic acids. To detect gold when combined with sulphur, iron, etc., requires a process too long to describe here, and altogether too difficult for one not accustomed to such work.

Drained Marsh.—"M. W. J.," Mayfield, Mich. The drained marsh intended for cranberries, but which will not grow either corn or oats, will probably improve after a year or two of cultivation. It may be that the soil contains too much of the injurious peroxide of iron, which frequently occurs under such circumstances, but will be changed to harmless compounds, after continued exposure to the air. An application of lime—say, 25 bushels per acre—might be beneficial. Ashes on such land seldom are of much value. Corn, oats, and rye usually succeed best on land like this for the first few years.

Horses and Cattle Together.—"H. F.," Evansville, Ind. So long as the animals are properly secured, there is no good reason why horses and cattle can not be kept under the same roof, without injury to either.

The Best Agricultural College. is asked for by "L. H. J.," of Wellsboro, Pa., "for a young man who has a good English education, and has had some years' practice on a farm; who is not afraid of work, and wishes to become a *first-class* farmer, or none at all." We can not say which is best, having had experience with only a few. Would recommend the Mass. Agricultural College, Amherst, Mass., or the Michigan Agricultural College, Lansing, Mich., or Maine College, Orono, Me.—these being known to us personally as doing good work as *agricultural* colleges.

Carbolic Acid for Sheep-dip.—"J. W. C.," Bates Co., Mo. We would advise you not to use unprepared carbolic acid for a sheep-dip. It is unsafe for such purpose, as one cannot tell how diluted or concentrated it is, and it may be absorbed by the skin and act as a poison. A good article is "Buchan's Cresylic Sheep-dip," of which carbolic acid is the basis. For some reasons it is preferable to tobacco.

Sheep Scab.—"J. S. McC.," Iola, Kansas. When Sheep pens and pastures are once infected with scab, three years may elapse before the insect and the eggs will perish. But the pens may be freed from the infection by a thorough washing with lime wash, containing carbolic acid at the rate of one hundredth part, mixed with it. The scab disease may be cured by washing the sheep in the preparation referred to in the preceding item. The sheep should be thoroughly soaked; the scabs be broken up and the raw surfaces well washed.

Shorthand.—"L. H. Y.," Yostville, Pa. Any person of ordinary intelligence can learn to write shorthand, but it requires a great deal of practice to become expert. Graham's book is good; some prefer Munson's.

Cutting Cows' Tails.—"A. E. H.," Harmony, Kan. We mean what we say, when we state that it is unnecessary ever to cut off a cow's tail. There is no such disease as tail-ail; nor do we, or any intelligent veterinarians, know of any reason why the tail should ever be cut. "B. V. B.," Monson, Mass., who thinks very highly of the *American Agriculturist*, asks, what to do instead of cutting the tail, to prevent the hair from curling? Well, if one doesn't like the curl, he may cut it off; but we do not see why a cow should not wear one curl, especially as it does no harm.

All We Know.—A subscriber, residing we don't know where, wants us to inform him "all we know about farming, and also the quantity and best ingredients of fertilizers." "W. A. W." does not ask much of the editors in his first request; but they cannot answer the second, unless he tells something of what he knows about what he wants to use the fertilizer for, and where he lives.

The Mole Drain-Plow.—"W. B. E.," Plymouth, Ill. The mole drain and sub-soil plow is effective in stiff clay lands. Upon light soils the opening made by the plow soon caves in and fills up.

Breachiness in Cows.—"G. W. H.," Stony Point, N. Y. We can suggest no plan to keep cows within bounds that are able to creep under bars only 18 inches from the ground. We fear such cows might fly over the stone walls. For the walls, with ordinary cows, it might be useful to plant stakes on each side, to which a rail is fastened with wire. For the bars it might answer to put a lower bar six inches from the ground. A cow that will creep under that is incor-

rigible, or too small to be worth keeping. If they work the bars out, bore holes in the ends and insert pegs.

Potash on Fruit Trees.—The "Gardener's Chronicle" (London, Eng.), quotes a correspondent of an American paper, as to the value of *potash* on trees, and his method of applying it, which is to slice up "a few bars of common soap," and bind the pieces in the branches where the rain will dissolve the soap and carry it down over the bark. This is no doubt excellent practice, but it is very strange that so accurate a paper as the "Chronicle" should regard this as a method of applying *Potash*. It surely knows that hard or bar soap does not contain potash. All hard soaps are soda soaps, but are not on that account the less useful to the tree.

Fruit-Growing in the United States.—The magnitude of the fruit-growing interest is not appreciated by many people. Col. Marshall P. Wilder, Pres. of American Pomological Society, in the last Report of the Society, makes the following estimate: Acres in fruit, including grapes, 4,500,000. Apple and Peach trees each 112,000,000. Pear trees, 28,000,000. Grape-Vines, 141,000,000. Value of annual products: Apples, \$50,400,000; Peaches, \$56,135,500; Pears, \$14,130,000; Strawberries, \$5,000,000; Grapes, \$2,118,900; other fruits, \$10,000,000. Total, over \$138,000,000, equal to half the average value of the entire wheat crop. This would give an average of over \$3 worth of fruit for each man, woman and child in the whole country—or over \$1.00 worth of apples, and the same of peaches.

Houdans and Hedge.—"B. H.," Iowa. The fowls take their name from a town in France. With us it is usually pronounced as if spelled *Hoo-dan*, but the French pronunciation, as well as it can be expressed in print, is *Hoo-dong*, as if it were written *dong*, with the *g* silent or nearly so. A sound which can only be properly learned by hearing it pronounced. . . . Your hedge may be ent in the fall.

Potato Diggers.—"R. D. M.," Wilnot, N. S. To use such an implement, good judgment is required to adapt it to the peculiar circumstances of each case. A man may be a good plowman, and yet require practice to become expert with a potato-digger. If it runs either too deep or too shallow, and will do both, it is certainly possible to make it hit a proper depth. We advise you to try again this season.

P. and P. B.—Petunias and Potato-Bugs. "E. C., an old Subscriber" in Wis., sends us a slip cut from some paper, to the effect that some one's potatoes escaped because "Wild Petunias" (whatever they may be) grew near the patch, and the bugs, being attracted by the Petunias, were poisoned by them. We do not know what is meant by "Wild Petunia," as we have no native species of Petunia, but in gardens the plant is frequently self-sown, and becomes in a measure a weed, and this is probably what is referred to. However, our correspondent states that he, several years ago, found the ground under a Petunia in his wife's flower-bed covered "nearly two inches thick (!) with dead potato-bugs, though said bed was on the outside of the house, and some distance from the potato-patch." He asks, if it would not be well to plant Petunias among the potatoes. Here is something worth following up, that we may learn its value.

Potatoes above Ground.—W. S. Parsons, of Md., sends us a potato vine on which are potatoes in various degrees of development, from fair-looking tubers, of the size of a butternut, down to that of a hazelnut, part tuber, and part branch. Such specimens are not of rare occurrence, when the growth of vines is so luxuriant as to exclude the light from the lower part of the stems. The potato proper, or tuber, is an underground stem, greatly enlarged by the deposition of starch. In cases like the present, the stem, being in the dark, does not develop as it would if exposed to the light, but thickens up, and makes a more or less perfect tuber. We figured a similar instance as long ago as April, 1863.

Blasting Logs.—"Progress" writes that a better way to tamp a hole for blasting a log, than driving in a plug beside the fuse, is to tamp with dry clay, brick-dust, or sand, even. He says the plug will blow out, but the tamping will hold every time.

Plums Do not Bear.—"S. A. D.," Lowell, Mass., writes: "Some Damson plum trees, six years old, are healthy and vigorous, and situated in a garden that is well cultivated. They were loaded with fruit one year; since then they have had none. What can be done to make them bear?" . . . This is one of the many unsatisfactory inquiries that we are asked to answer. The writer thinks that the whole story is told, but he has really told but little. If the trees have bloomed freely, since the "one year" of bearing, but of which nothing

is said, we should look to the *Curellio*, as the probable cause of unproductiveness. The attack of this insect begins as soon as the fruit is set, or is as big as peas. We should look for no other reason for lack of fruit, unless assured by good observers that it was *not* the *curellio*. If so, as likely to be the case, there can be no fruit, unless the *curellio* is daily jarred from the tree, as we have described over and over, and are willing to describe again. If the trees bloomed, the chances are 99 to 100, that the *curellio* was the trouble. If the trees did not flower, then we should look for another cause.

About Bleaching.—"J. H.," Minneapolis. We have so frequently stated that we do not answer anonymous letters, that we infer you are a new subscriber, and not aware of this rule. Had you given your address, we should be able to ask for a more definite question, as it is not possible to answer one so general in terms as yours.

Exhibition of the American Institute.—It is announced that the 47th Exhibition of the American Institute will be opened September 11th; and closed November 16th, 1878.

Department of Agriculture.—The resignation of J. R. Dodge, statistician, is announced just as we go to press. No reasons are given for a step which deprives the Department of an industrious, useful officer.

Natural Sciences at Brown University.—The Corporation of Brown have recently appointed Prof. A. S. Packard, Jr., the well known entomologist, of Salem, Mass., to the new chair of Geology and Zoology.

To Keep a Road horse in Condition. we would say to "A. G.," Hamilton, Ont., requires regular feeding with the best food, good grooming, and a clean, well-ventilated stable. A good course of feeding may be as follows: A three-peck basketful of cut-hay moistened and mixed with three quarts of ground feed, of corn, oats, and wheat-bran, to be given morning and evening. At noon, four quarts of sound, crushed oats. At night, a few pounds of long-hay. With each feed, a tablespoonful of salt should be given. If the animal is rough and hide-bound, give a quart of linseed-meal at each meal, in place of as much ground feed.

Nuts and Nubbins.

The msketo, like charity, begins to hum. Ten hot sun-days, all together—in June 1878. That horse is not much at running fast, but he can stand the fastest of any horse you ever saw. Scientific agriculturists speak of the "fruit belt" of the South. It is where green apples strike the small boy. A little girl yesterday, while watching the rain, turned to her mother, and said: "Ma, I guess the weather's so warm it's melting the clouds."

A cynical old practitioner says, "A lady who practises medicine commits two faults: she increases the number of doctors and diminishes the number of women."

"Your dog, what does he want here?" inquired a dry goods dealer of a customer whose big Newfoundland was upsetting things generally. "Muzzlin," was the answer.

Statistics show that the number of idiots is increasing; and yet some newspapers continue to make war on quack doctors. What's a quack doctor for but to kill off fools?

"When tempted to kick a man," says a Scotch philosopher, "stop and remember that you may some day want a favor of him." Tempted men generally stop to see if the other fellow is the biggest.

A boy of four will ask questions which the man of forty can't answer. Even Darwin's children can puzzle their father if they will only say to him: "Where that first hen came from, is what I want to know."

"Vat a monster language," said a Frenchman; "here I read in ze newspaper zat a man commit a murder, was committed for trial, and zen committed himself to a reportair. No wonder everyzing in America is done by committee."

On the Fourth a native American was upbraiding a naturalized German for celebrating the day so enthusiastically. The German replied: "You, sir, are an American from necessity; I am one from choice. And beside, sir, when you came into the country, you hadn't a stitch of clothing to your back, while I was comfortably clad." The American has been thinking about it ever since.

Work on the Boston Post-office extension is progressing slowly but surely. Four masons squinted over a block of stone yesterday for three hours to decide if it was level, and then went to dinner. A couple of men who spent the principal part of the afternoon in getting in and out of their overalls, got as far as spitting on their hands before it was time to "knock off." They will lift a couple of planks early in the week.—*Boston Paper*.

ORANGE JUDD COMPANY, 245 BROADWAY, NEW YORK.

Farmers Friend Grain

And Fertilizer Drill.

The quantity is regulated with gear-wheels in a **CONE**, and controlled by a **Lever**, so there are no loose wheels or movable feeders, and it will sow any grain perfectly and accurately.

It has the best **Spring Hoe**, and every Drill has a **Force-Feed Grass-Seeder, Patent Shifter, and Surveyor** free.

Illustrated Catalogues, with description, prices, and a **Full Centennial Report**, sent on application. Agents wanted in unoccupied territory. Address, stating where you saw this notice,

FARMERS' FRIEND MANUF'G CO.,
Dayton, Ohio.

STEAM ENGINES,

A. B. FARQUHAR, York, Pa.

Cheapest and best for all purposes—simple, strong, and durable. Also *Traction Engines* for common roads.

SAW, GRIST AND RICE MILLS, GINS, PRESSES AND MACHINERY generally. Inquiries promptly answered.

The Farquhar Separator

(Warranted)

Feeds Agricultural Works, York, Pa. Lightest draft, most durable, simplest, most economic and perfect in use. Wastes no grain, cleans it ready for market.

Send for Illustrated Catalogue. Address A. B. Farquhar, York, Pa.

Use the Anti-Friction Hay-Carrier,

For elevating and conveying Hay, Grain, etc., in barn, bar-rack, shed, or field. It elevates perpendicularly and conveys horizontally any desired distance. No trouble about getting over high beams and to the end of deep mows, or to the top of high stacks. **Thousands are now in use.** Five tons have been stacked and the frame moved in 45 consecutive minutes. Fifty tons have been stacked in single day with this Frame and Carrier. Send for Circular "2" to **U. S. WIND ENGINE & PUMP CO.,** Batavia, Ill.

A Most Delightful Residence

FOR ANY FAMILY.

EDUCATIONAL Advantages UNSURPASSED, from Primary Schools up to the best COLLEGIATE.—Society most Desirable in every respect.—CITY and COUNTRY advantages admirably combined.—One of the most attractive Residences for a well-to-do family, in one of New England's most beautiful "City-towns"—For SALE or to LEASE, for one, two, or three years, furnished or unfurnished, on very favorable terms, at a very low price. For particulars, address "RESIDENCE," care of *American Agriculturist*, 245 Broadway, New York.

NEW ECONOMIZER

AGRICULTURAL ENGINE.

The cheapest, most economical yet powerful Engine in the market; and is the *only* Agricultural Engine with *Return Flue* Boiler in use.

There is no obstruction whatever to the draft, yet the returning of the flames through the small tubes compels the deposit of the great body of sparks in the chamber rear of the boiler.

It is the best and safest Steaming Boiler in use, and we invite competition with any first-class maker. It will make more steam from less fuel than any horizontal boiler built. Before buying, see one or send for full particulars, circulars, etc., which will be sent free by addressing

WHITMAN & BURRELL,
Little Falls, N. Y.

Also Manufacturers and Dealers in Cheese Factory Outfits and Supplies.

N. B.—The Economizer Boilers are manufactured for us (in duplicate parts), under United States patents, by Porter Manufacturing Company, Syracuse, N. Y., thus securing perfection and uniformity. The demand is unprecedented, even in these dull times.

BOOKWALTER ENGINE.

Compact, Substantial, Economical, and Easily managed. Guaranteed to work well and give full power claimed. Engine and Boiler complete, including Governor, Pump, &c., (and boxing), at the low price of

CLAWSON WHEAT for Seed. Samples free to any address.

Automatic Cow-Milker.

I have the best and simplest milker in the world, made all of pure silver. It is easily kept clean, and has no flexible or rubber tubes, to sour and spoil the milk in warm weather. It is easily applied, and can be seen while milking that every teat is flowing.

Will milk sore or short teats, or klieker. Fractious cows become very gentle by the use of my milker. It is the cheapest, best, and only perfect milker. It never gets out of order—never wears out. It will milk any cow very quick. Price \$3.00 per set; two sets, \$5.00. Single Tubes, 75 cents. Full directions. Agents wanted for every County in each State. WM. F. ELY, P. O. Box 226, Madison, Morris Co., N. J.

WILLIAM CROZIER has much pleasure in calling the attention of Cow-keepers, Farmers, and Dairymen to the NEW SELF-MILKING APPARATUS. This Apparatus or Cow Milker, has been tested by a large number of practical Agriculturists, Dairymen, &c.; and without exception, merited high eulogiums and commendations, for its adaptability and wonderful rapidity in the Milking of Cows. It is considered one of the most valuable and useful Machines yet invented.

Amongst its many advantages are—

1st—It is SELF-ACTING, easy of application; and can be used by any person, however ignorant of Milking.

2nd—It will Milk any Cow in FOUR Minutes effectually, and its use is more agreeable to the Cow than Hand-Milking.

3rd—It is a great boon in the case of Sore or Corded Teats.

4th—Its Usefulness, Simplicity, Saving of Time, Cleanliness, Durability, and Cheapness, prove it to be a most important and necessary adjunct to Dairy, and it has only to become better known to be universally used.

Sent free on receipt of Post Office order for \$5.

Printed Instructions accompany each Machine.

All infringements will be vigorously prosecuted.

MILK TUBES.

COW-KEEPERS should not be without one of these, as they are invaluable for sore or Corded Teats.

PRICE \$1.00 each.

WM. CROZIER, Northport, L. I., N. Y.

A FARM BOOK-KEEPER WANTED.—Age from 15 to 18; one who desires to learn practical farming. Good references required. Pay small. Address: E. H. L., American Agriculturist, 245 Broadway, N. Y.

THE "Model Piano."

PRICE \$150 to \$200.

The "Model" is a beautiful little Upright or Cottage piano; it is manufactured from the best materials that can be procured; the workmanship is excellent, and its durability is guaranteed; it is small, light, and occupies but little room, is easily transported, and above all the "Model" is sold at about one-third the price that is usually paid for any other reliable piano. For the above reasons, it is very suitable for people of moderate means, and those living in small houses; but it is especially adapted for beginners, and on account of its low price, commends itself to every parent, because it possesses all the principal features of the finest piano, and has none of the numerous disadvantages of the cheap organ.

For full particulars write for illustrated pamphlet, and state where you saw this notice.

THE

SPORTSMAN'S LIBRARY

OF

1878.
STANDARD BOOKS.

ORANGE JUDD Co.,

245 BROADWAY,

New York.

*From Forest and Stream.*

SPORTSMAN'S LIBRARY.—Messrs. Orange Judd Co., of New York, have just issued their catalogue of the Sportsman's Library. This list contains all the best and reliable books which have been published in the United States on these interesting topics. Not only does the Orange Judd Catalogue contain the characteristics of birds, fishes, horses, and dogs, but natural history finds its place. We may mention among the latter "Baird's Birds of North America," with Wilson's and Coues' works on Ornithology. Text books on rifle shooting, including "Wingate's Rifle Practice," "Rifles and Marksmanship," by Judge Gildersleeve, are offered. Among the standard books are "Hallock's Gazetteer," and all Forester's works, with the leading treatises on Fish Culture, etc. The Judd Catalogue is in fact a complete compendium.

From The Spirit of the Times.

SPORTSMAN'S LIBRARY OF STANDARD BOOKS, just issued by the Orange Judd Company, 245 Broadway, New York, is a very interesting compilation of the various works—American and English—pertaining to hunting, fishing, and other out-door sports and pastimes. It is printed on tinted paper, presents an outline of over one hundred and fifty publications, and contains between eighty and ninety illustrations of game birds, fish, horses, etc., many of them drawn from life, and portraying their points and characteristics. This compilation meets a want that has been felt, as sportsmen and others can find enumerated and described in it, the various books they may require. Prominence is given to Judge Gildersleeve's volume on "Rifles and Marksmanship." Send to them for a copy.

THE

Sportsman's Library

OF

STANDARD BOOKS.

JUST ISSUED.

This Compilation Contains Brief Descriptions of Over One Hundred and Fifty Books Upon Out-door Sports and Amusements, Together with Between Eighty and Ninety Spirited Illustrations of Game Birds, Fish, Horses, etc., Many of them Drawn from Life.

Opinions of Sportsmen and the Press.

From the HON. N. P. STANTON, President of the National Rifle Association of America.

This is a most valuable compilation, which should be in the hands of every sportsman; every one who wishes to acquire the art of shooting, or to obtain information regarding game birds, fish, horses, guns, equipments. The trouble hitherto has been that people have not known what works were issued on out-door sports and pastimes, or where they could be procured. This compilation supplies all the needed information. Over one hundred and fifty publications are here grouped under their respective heads, together with brief illustrations, and between eighty and ninety spirited illustrations.

From COL. WM. C. CHURCH, Editor of the Army and Navy Journal, and Ex-President National Rifle Association.

MESSRS. ORANGE JUDD COMPANY:

Gentlemen:—I am glad to see that you have gathered together into one library the standard works for sportsmen, and have issued a handsome illustrated Catalogue of such publications. The demand for such a collection, which undoubtedly exists, is gratifying evidence of an increase of interest in manly pastimes, which should save us from that fate as a nation of sour-visaged dyspeptics, to which some foreign observers have too hastily condemned us.

From MAJ. HENRY FULTON, Captain of the Victorious American Rifle Team of 1876.

All who are interested in sporting matters and out-door amusements, will be gratified by the publication of the above named Catalogue by the Orange Judd Co., as it embraces all of the best publications on field sports, etc. To know the contents of the books mentioned in the list will fit any man for the better employment of his time, and if the knowledge to be gained in this way is practically employed, better health and longer life will be the result.

From GEO. S. SCHERMERHORN, JR., Secretary National Rifle Association.

A WELCOME AND MUCH NEEDED PUBLICATION — Perhaps no inquiry is more frequently made of one known to be interested in out-door sports and amusements, than "Where can I find a good text book upon this or that sport, and what is the title and price?" Here we find answers to each of these questions, and that in a very acceptable form.

Winter Greeneries AT HOME.

By Rev. E. A. JOHNSON, D. D.,
Author of "Half Hour Studies of Life," etc., etc.
FINELY ILLUSTRATED.

This Volume differs from most other works on winter gardening, in giving the results of actual practice. The author for several years past has found recreation in beautifying his study with plants; his work has resulted in so much enjoyment to himself and his friends that he has been induced to tell what he did, and how he did it. The book is not a mere dry set of directions, but its teachings are presented in the pleasant form of letters to some young ladies, who, having witnessed the author's success, have asked his instruction, and this allows a genial personality to pervade the work, and makes it withal readable, as well as instructive. It is a most excellent guide to successful winter-gardening, as suited to American homes, with our peculiar domestic surroundings, and those who follow its teachings will reach a satisfactory measure of success. The engravings include several representations of the author's study.

12mo. PRICE, POST-PAID, \$1.00.

ORANGE JUDD CO., 245 Broadway, New York.

JUST PUBLISHED.

FERNS

In their Homes and Ours.

A New and Useful Work upon

FERN CULTURE.

By JOHN ROBINSON,

Professor of Botany and Vegetable Physiology, etc., to
the Massachusetts Horticultural Society.

Mr. Robinson has long been known to us as an accurate student of Ferns, and as an enthusiastic cultivator of both hardy and greenhouse species, and is abundantly qualified, from both scientific and practical knowledge, to treat the subject. This work is especially valuable, as it was so much needed, and it is fortunate that the first attempt of the kind in this country should come from the hands of one so thoroughly competent, as the author.

The work, a large 12mo. of 175 pages, is not a mere manual of Fern Culture, but is really a Compendium of

THE HISTORY OF FERNS,

Describing their peculiar structure and manner of growth, and giving an account of their wonderful development from the spore. The chapters on classification, distribution, and names, are well adapted to the wants of the popular reader, and its summary of the Literature of Ferns is a useful feature.

THE PRACTICAL INSTRUCTIONS

for the construction of Out-door Ferneries, the Collection of Ferns, Selection of Soil, Pots, Fern-Cases, etc., are the results of long and successful experience, and can not fail to increase the cultivation of these interesting plants. The work is produced in exceedingly neat style, and abundantly illustrated with plain and colored plates.

12mo. PRICE, POST-PAID, \$1.50.

CAUTION TO THE PUBLIC.

To avoid imposition, purchasers of Waltham watches will observe that every genuine watch, whether gold or silver, bears our trade-mark on both case and movement.

Gold cases are stamped "A. W. Co." and guarantee certificates accompany them. Silver cases are stamped "Am. Watch Co., Waltham, Mass., Sterling Silver," and are accompanied by guarantee certificates, signed R. E. Robbins, Treasurer. The name "Waltham" is plainly engraved upon all movements, irrespective of other distinguishing marks.

This caution is rendered necessary by reason of the fact that our cases are frequently separated from our movements and put upon worthless movements of other makers, and vice versa, thus affecting injuriously the performance of the watches and vitiating our guarantee, which is intended to cover only our complete watches wholly made by us. It is necessary also because it is so notorious as to be a public scandal, that there is great fraud in the metal quality of both gold and silver cases as now generally sold. We have demonstrated by frequent assays that many gold and silver cases offered in the market are debased from 10 to 20 per cent from the quality they assume to be. This is a fraud upon the purchaser, and accounts for the low price at which such cased watches have been sold.

"Eighteen carat" gold, such as the Waltham cases are made of, is as nearly pure gold as can be made and be durable. It contains 750-1000 of pure gold, and 250-1000 of alloy.

Sterling Silver (English Govt. standard) contains 925-1000 of pure silver, and 75-1000 of alloy. The Waltham Watches will always be found up to the standard represented.

Terms, Publishers' Notices, etc.

Price Reduced; Quality not Reduced.

New Subscription Rates of the American Agriculturist.

The great element of cost in supplying a Journal is the expense of paper—especially one of *this* kind, which is printed on sized and calendered paper of *strong fibre* (made of pure white cotton and linen with no mixture of clay, straw, or woody fibre now so generally used). It is necessary to use this, as a large proportion of the numbers are each handled and read by many persons; they are kept in use for a month or more, and very many are preserved by binding or stitching. The theory of the Publishers has been to make up any thing saved in lower cost of paper, by adding to the quantity, and the quality. When the price of paper fell enough to allow it, the tinted Cover was added, with its five new engravings (the center and four corner pieces) upon every successive number. About \$20,000 a year are expended in gathering information, editing, and engravings, and \$7,000 to \$8,000 in type-setting and electrotyping—all this before going to

the press. Taking into account the cost, the care, and the quality, there is no doubt that the *American Agriculturist* has long been one of the cheapest Journals in the world, and the wonder has often been expressed, how it could be afforded so low.

BUT

Every added subscriber increases the number among whom to divide general expenses of editing, engraving, type-setting, electrotyping, office-help and supervision, and our friends have so largely increased the circulation the present year, and promise so much for the future, that the Publishers have determined to **Reduce the Price still further, without at all diminishing the Value of the Paper.** Indeed, they will continue to increase its real value to the readers. The Publishers propose to hereafter assume the entire expense of prepaying postage themselves, amounting to over \$10,000 a year. The price will also be reduced to smaller clubs, and so simplified that all clubs can be forwarded without the use of fractional currency, as follows:

For One or Two Subscriptions, One Year, the price will hereafter be (post-free) \$1.50 each, instead of \$1.60. (For 15 months, now, \$1.80.)*

[ALL POST FREE.]		For 15* months.
Three Subscribers one year,	\$1, or \$1.33 each.	\$1.65
Four Subscribers one year,	\$5, or \$1.25 each.	\$1.55
Five Subscribers one year,	\$6, or \$1.20 each.	\$1.45
Six Subscribers one year,	\$7, or \$1.17 each.	\$1.40
Seven Subscribers one year,	\$8, or \$1.14 each.	\$1.35
Eight Subscribers one year,	\$9, or \$1.12 each.	\$1.30

Ten or more Subscribers, post-free, Only \$1 each..... \$1.25

[*These 15 month's terms are added to accommodate those who may wish to begin with the October number, and continue through 1879, a period of fifteen months.]

Single Numbers sent, postpaid, for 15 cents each. Specimen numbers for examination sent, postpaid, for 10 cents each. Subscriptions can begin at any time.

The above terms are for the United States and Territories, and British America. Add 11 cents extra per year for papers delivered by mail in N. Y. City, and for copies sent outside of the United States and British America, except to Africa, Brazil, British Honduras, the East Indies, and Mexico. For the last named five countries the extra charge is 38 cents per year, to cover extra postage; Single Numbers, 17 cents, post-paid. Remittances, payable to Order of Orange Judd Company, may be sent in form of Checks or Drafts on N. Y. City Banks or Bankers; or P. O. Money Orders; or in Registered Letters, such letters to have the money enclosed in the presence of the Postmaster, and his receipt taken for it, and the postage and registering to be put on in stamps. Money remitted in any one of the above three methods is safe against loss. Bound Volumes from Vol. 16 to 36 inclusive, supplied at \$2 each, or \$2.30 if to be sent by mail. Sets of numbers sent to the office will be bound in our regular style for 75 cents (30 cents extra if to be returned by mail). Missing numbers in such volumes supplied at 10 cents each.—Any Numbers of the paper issued for 21 years past, sent post paid for 15 cents each; or any full year, sent unbound, for \$1.50. Clubs of Subscribers can be increased at any time, at the club rates, if new members begin at same date as original club.

A GOOD WATCH for EVERY-BODY.—To Be Obtained FREE, or for a Very Little Money.—A really valuable, very desirable, reliable time-piece. For particulars, see page 354 of this paper.

Every German Cultivator and Laborer on the Farm, or in the Garden, OUGHT to have the German *American Agriculturist*, and thousands of new subscribers are taking it this year. It contains not only the Engravings and all the essential reading matter of the American edition, but an additional *Special German Department*, edited by the Hon. Frederick Münch, of Missouri, a skillful and successful cultivator and excellent writer. No other German Agricultural or Horticultural Journal in America has been so long issued; no other contains so much useful information and so many engravings.

Reliable Business Men, those who have both the *ability* and the *intention* to do what they promise, are the only ones invited to use the business-pages of this journal, and those in charge of that department are under positive instructions to admit no others at any price, and they try to live up to it, and generally do, though once in a while they may make a mistake—to err is human—but *this* seldom occurs. We could make a fortune in a single year, and supply the paper at lower rates, if the advertising pages were thrown open to those who gladly pay high prices, as they can afford to, because they give little for much. But we mean our advertising pages shall be a valuable source of *trustworthy* information to our readers.—When ordering from, or corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of this Journal. They will know what we expect, and what you expect of them as to prompt and fair treatment.

Trade With Sandwich Islands.—Mr. J. B. Castle, a resident of Honolulu, referring to Mr. Bellamy's article in the *American Agriculturist* for August, says: The history of the reciprocity treaty, and the statistics of trade between the United States and Hawaiian Islands, show the treaty in a highly favorable light. It is not a mere question of the absolute amount of coin paid into the U. S. Treasury, but a choice between a small inactive trade, and an intimate, prosperous commercial relation between this country and a natural source of supply for the Pacific Coast. The report of the Statistical Bureau at Washington, shows the *increase* alone of our exports to the Sandwich Islands to be nearly equal to the amount annually paid for duties previous to the treaty. Its tendency steadily and strongly turning trade from other countries to this, and assisting our manufacturers to a free competition in supplying the Islands. Could you give the space, it would be easy to show any intelligent and thoughtful inquirer the real *reciprocity* of the treaty. For want of time and space I omit reference to other statements of Mr. Bellamy—but I hope all interested will refer to the statistics and reports of the working of the treaty, published in Washington, April 17, 1878.

Advantages of a Feed-Cutter.—"A. D.," Du Quoin, Ill., writes, that in 1871, he had 30 acres of land, 4 cows, and a pair of mules, for which he found it difficult to provide fodder. For economy, he bought a feed-cutter, and then had plenty of feed and increased his stock. This increased his manure, and that doubled the supply of feed. The stock was again added to, and at present there are 22 head of cattle and horses on the 30 acres, and more feed than can be used. He now has a steam engine attached to a large-sized cutter. His prosperity dates from the day he used a fodder-cutter.

Simple Signals for Rifle Ranges, Farmers, etc.—Since sending page 347 to press, several trials have been made of "talking at a distance," with gratifying results. After a few minutes' practice, a boy at a distance called off the numbers 23, 3, 23; 322; 21, 1, 113, 113; 32, 11; 11, 212, 2, 133; 322; 211, 1, 132, 32, 2, 211 ("did the ball go over the target?") almost as fast as we could indicate the figures with our hands, and he promptly signalled back with his hands: 122, 11; 3, 211; 213, 2, 122, 211; 211, 11; 322; 132, 3, 32, 33, 211 ("Ad; it went to the right"). In shooting at long range, 500, 800, 900, or 1,000 yards, it is desirable to be able to readily communicate with the marker, and this mode will be found very convenient. Even if the whole alphabet be not used, it will be easy to arrange a few numbers to represent the most common requirements, as 132 for: "Repeat your examination of the target" (right hand up, left hand out, right hand out, 1, 3, 2), and so of other sentences. Hunters can use this sign language for silent communication about game appearing, or otherwise. The *Farmer*, by having the table of letters and numbers learned by all on the farm, which can be quickly done, will have the easy means of communicating with men or boys in distant fields, and thus save a world of steps.

Winter Oats.—"G. H. A." An experiment with winter oats last season was a complete failure with us. They grew until the latter part of the winter, when every spike was destroyed. We do not advise any one to risk sowing them for a crop, so far north as the latitude of New York, until tested in a small way first.

North Carolina is having good work done in its Agricultural Department, by Dr. Le Duc, its chemist, in the important fertilizer question. His labors have tended to place the manufacture and trade on a reliable basis, which means much when it is considered that about one million dollar's worth of fertilizers are sold and used in that State every year. We understand that preparations are now being made for more extensive experimental work and investigations under the auspices of the Department, and that an excellent assistant chemist, Mr. Geo. Warnecke, who first came from Germany by invitation to the Connecticut Agricultural Experiment Station at Middletown, has already been engaged.

Bat Guano.—"W. W.," Round Rock, Tex. This manure is not yet in the market as a commercial article. Its composition varies widely, according as it is pure, or mixed with inert matters, or been wet or dry. It is especially valuable for the nitrogen it contains, the proportion of which varies from one to ten per cent; it also contains from $\frac{1}{4}$ to $\frac{1}{2}$ per cent of phosphoric acid. Its value, compared with commercial fertilizers, is from \$10 to \$10 per ton. Bat guano, found in the caves frequented by these animals, will make a good manure, especially for grains, but may also be used with profit on any crop requiring a strong manure, *not* rich in potash.

Tomato Catsup.—There is a wonderful difference among the various articles called Tomato Catsup, from the rich sauce, so thick it will hardly pour, to the thin, watery stuff that would not keep but for the vinegar and salt it contains. Every family should make its own, not only as a matter of economy, but of safety. If one *must* buy, avoid the bright red attractive looking compounds, as they are artificially colored. The cheap stuff sold to restaurants is made from the peelings and other refuse of the canning factories. Good catsup can only be made when the fruit is in perfection; towards the end of the season, when the nights get cool, and growth is slow, the fruit is watery, and will not yield the rich pulp of the best fruit. Select ripe tomatoes, cutting away any green portions, cut in pieces, stew until thoroughly done, and rub through a sieve fine enough to retain the seeds. Evaporate what passes the sieve to the desired thickness; for this, no rules by quantity can be given, as a bushel of some tomatoes will yield twice as much pulp as others. The evaporation should go on over a slow fire, being careful not to scorch it. When thick enough to pour from a cruet, without inconvenience, add salt and spices. Here the recipes give the greatest possible variety. Be sure and use salt enough; a chopped onion, or clove of garlic, tied in a cloth and cooked in the pulp, to give *just a suspicion* of the flavor, is liked by many; Allspice, Black Pepper, Cayenne, and Mustard, are the principal spices, and are used according to the taste of the consumers. One recipe directs for a half bushel of tomatoes; Cloves, two teaspoonfuls, Cinnamon, Allspice, and Black Pepper, two tablespoonfuls each; these are not to be ground, but bruised, placed in a little bag and boiled in the pulp while it is being evaporated; when the pulp is thick enough, remove the bag and add Mustard, ground, two tablespoonfuls; Cayenne Pepper, two teaspoonfuls; good Vinegar, two quarts, and salt to the taste. Another recipe uses all ground spices, viz.: For the pulp from $\frac{1}{2}$ bushel of fruit: Allspice and Cloves, $\frac{1}{4}$ oz. each; Mustard, $\frac{1}{2}$ oz. Black Pepper, 3 oz.; Mace, $\frac{1}{4}$ oz.; Cayenne, $\frac{1}{2}$ oz.; Salt, 6 oz. or sufficient, and Vinegar, 2 qts. Add the spices, boil a minute or two, cool, and bottle.

Cucumber Catsup.—This recipe, given several years ago, is republished by request. Take overgrown cucumbers, before they turn yellow, peel, and grate on a very coarse grater. Allow the pulp to drain on a colander, then sift through a coarse sieve to separate the seeds. Half fill wide-mouthed bottles or preserving jars with this pulp, and fill up with good vinegar. When served, add salt and pepper. It has precisely the odor and flavor of fresh cucumbers, and makes an acceptable accompaniment to cold meats. In our first attempt at making this, finding no grater coarse enough, and buying a large cover which had outlived the wash-boiler to which it belonged, using a large nail, we converted this into a grater, which, if not handsome, was efficient.

Lassell Seminary, Auburndale, Mass., presents features too seldom found in educational institutions for girls, in being especially strong in those branches of study bearing on domestic life. The practical methods of training adopted, are spoken of in high terms by people familiar with the working of the school.

Pasturing Grass Fields, especially newly-seeded stubbles, is a bad practice, and recognized as such by most good farmers in this country. In other countries, and in sections of this where the ground does not freeze hard, it may do no harm, indeed be a positive benefit to graze fattening animals on grass fields, as then there is no danger of damage by frost, and the droppings

of the cattle serve to enrich the land. But in the colder regions, the grass roots want all the protection from frost that the uncultured aftermath provides. Instead of feeding such lands, particularly those newly seeded, it is more profitable to fertilize them, either with a fine compost or some artificial fertilizer. Fall applications of manure strengthen and multiply the grass roots, and put the plants in a vigorous condition to withstand the winter, and for an early start in spring. All fertilizers should be applied to grass as early in the season as possible—better immediately after haying—so that it may be used in this season's growth. If not applied until late, much of it may be wasted by leaching in light soil, and washing away on heavy lands. It is said above that fattening cattle only were suitable for grazing grass fields. This is because that in the production of fat none of the elements of fertility—save those supplied in abundance by nature—are taken from the land, all of these being returned in the faeces. But a growing animal takes large amounts of phosphates for its bones, and of nitrogen for its muscle; and a milch cow takes phosphates for her milk; both take some potash. This fact should always be remembered, that mature fattening animals do not deteriorate the land, while growing animals and milch cows draw on its fertility.

Mistakes About Goats.—"W. H.," Watertown, Mass. Goats do not have kids four times a year, nor two or more at a birth. All hope of profit or fortune from such increase as that will have to be abandoned. Goats increase the same as sheep, and are no more prolific.

Packing Butter for Winter.—"Mrs. V.," Summit Park, Col. To pack butter for winter, begin when the weather is cool, and the butter can be kept hard. Free the butter from milk by repeated washing with cold spring water. Salt at the rate of one ounce to the pound, and set the butter away for 24 hours. Then re-work, getting all the milky brine away, and add one-fourth as much salt as before, to replace the waste. Then pack closely in layers two inches thick in clean, new, white oak tubs or pails, which have been scalded and soaked in brine. When the tub is full to the top, cover the butter with a piece of muslin dipped in cold water, and cover with salt. Fasten the cover, and put away in a dry, cool cellar.

Exports and Imports.—The family that produces and sells more than is bought, is growing richer. So with a nation. The official reports for the fiscal year up to July 1st, shows that this country sent abroad of its products to the amount of \$352,049,639, while it imported only \$285,757,455—a gain to us of \$76,292,184. The export of our products, exclusive of specie, were \$51,327,700 greater than for the year ending July 1, 1877, and \$77,808,842 greater than for the year ending July 1, 1876.

The Colorado Beetle.—Experience shows that we have this enemy in our power, if we only make use of the simple means at hand for putting an end to him. In many localities the beetles and larvae are but few in number, and the potato vines are strong and vigorous. For these reasons we hear farmers say, "the beetle is doing no harm, it is not worth while to bother with him." So the pest is left to gather force for another year. If every one possible were destroyed, but few would go into winter quarters, to appear next season. While the beetles are thus reduced in numbers, we may effectively prevent them from doing much harm next season, by poisoning all of the late brood wherever they may be found. This is a duty every man owes the community, and no one should be so selfish or numbing of other's rights, or convenience, as to neglect it.

The American Agriculturist in Japan.—S. Tsuda, Editor of the "No-Gio Lashi," the Japanese agricultural journal, mentioned some months ago, writes: "Let me assure you that your paper has been of great benefit to the Japanese.... It is my great desire to make the 'No-Gio Lashi' to Japan, what the *American Agriculturist* is to America and the rest of the world."

As to Sowing Wheat.—"T. S. C. H.," Essex Co., Mass. Very full directions for sowing wheat will be found in the monthly "hints for work." The soil must be well drained, or wheat will not thrive, and it will be liable to be heaved out by frost and winter killed. The Clawson wheat is now very popular. Wheat straw is of little value for feed, without a generous mixture of ground grain and roots, say corn and turnips; but neither of them is good for growing and fattening animals.

Information About Poultry.—"B. C. E.," Port Robinson, Ont. It would be misleading to give estimates of what can be done in poultry raising without knowing all the facts in the case. General information can be had from the following books: "An Egg Farm," by Stoddard; "Wright's Practical Poultry Keeper," and "Poultry Farm and Market," by Corbett.

American AGRICULTURIST.

NEW YORK, SEPTEMBER, 1878.

Agricultural Notes from Channel Islands.

From our Special Correspondent.

Jersey, Guernsey, Alderney, and Sark, lying just off the coast of Normandy, France—mere rocky isles, sprinkled about with hundreds of lesser rocks—are the so-called Channel Islands, dependencies of Great Britain, but not colonial possessions, and these together constitute one of London's most noteworthy kitchen-gardens, though three of them are known in America mostly for their cattle.

Potatoes are Jersey's great specialty, the season for which extends from the latter part of May to the middle of July, and a special potato steamer leaves St. Heliers daily for London. Guernsey's specialties are grapes, plums, figs, pears, cut flow-

oxen and one or two pair of horses, followed by the farmers with their hooks and forks, is a picturesque sight. Below is an illustration of such a team; it shows the peculiar cart and an odd form of yoke, which is a straight piece fastened behind the horns, with a straight rod extending half down each side of the neck, and a cord underneath, to serve as a bow. The number of men to each team shows an abundance of labor, which would hardly be economical in America. The price of *Herm vrac*, delivered in Sark, is from five to six shillings per ton, and it requires from 22 to 25 shillings' worth (\$5.50 to \$6.25) to manure an English acre.

Over 100 tons of grapes will be shipped from St. Peter Port, Guernsey, to London, this season. Hamburgs and Muscats are the chief varieties, and these are raised in greenhouses without artificial heat. We visited one vinery comprising 11 greenhouses, which will produce this year over four tons. Several hundred weight have already been shipped to London, where they brought from 2s. 6d. to 3s. 6d. (62 to 87 cts.) per pound, wholesale, and at this time they retail in London from 5 to 8s. per pound. The vines are placed about one

neys, to which they are similar in color and physique, but the Guernseys are generally larger and finer, and give more milk. The Guernseys are larger than the Jerseys, and in color are usually reddish-yellow and white, often curiously spotted with white, and have uniformly yellow skins. They give more milk than the Jerseys, and the butter is higher colored—indeed, so marked is the yellow hue that it is wrongly supposed by strangers, that Guernsey butter is artificially colored. Another important advantage claimed for them over the Jerseys is that they can be fattened for beef after having served their time as dairy cattle.

Pasture land is scarce and expensive. Grass must be economized, so all the cows are tethered. By this means their rations are given in known quantities, and they make the most of what comes within the scope of their tethers, instead of wandering about picking up the daintiest morsels and trampling down the rest. They are generally much petted, and are as docile as kittens. Singularly enough, considering the affection of their owners for them, they are seldom given proper names. In conversation, they are distinguished by such

COLLECTING SEA-WEED FOR MANURE IN THE CHANNEL ISLANDS.

ers, including camellias which flourish in the open air, and fresh fish. Sark supplies fish and rabbits, and the little island of Herm, rabbits, and *vraic* or sea-weed. The rabbits live among the furze, and are bred in immense numbers. During a recent season one boatman carried 7,000 from Herm to the Guernsey market, where they were sold for 10 pence (20 cents) apiece. Meat, with the exception of rabbits and chickens, is scarce in Sark and expensive, and milk brings 4 pence (8 cents) a quart; butter, 1s. 6d. (37 cts.) a pound; eggs, 1 shilling (25 cts.) a dozen; and a six-pound loaf of wheat-bread, from 1 shilling 3 farthings to 1s. 2d. (26 to 29 cts.).

Jersey produces a remarkable variety of cabbage, called the "Jersey Cow Cabbage," which grows to the height of four to six feet, and is cultivated for fodder. The stalk, which is tall and straight, is often made into walking sticks; this, when smoothed off and varnished, is similar in appearance to a bamboo cane, and most travellers who visit the island carry away a cabbage walking stick.

There is an old proverb current in the Channel Islands: "*Point de vraie, point de hautgard!*" which, being translated, means: "No sea-weed, no wheat-field!" *Vraie* is the local name for the sea-weed, which grows in immense quantities along the rocky shores, and which is used for manure. The season for gathering it is limited by law, and extends, I believe, from Feb. 1 to August 15. The live weed is torn from the rocks, and heaped upon the beach to dry, after which it is conveyed by carts to the fields. A *vraic* cart, drawn by a yoke of

foot apart, and are trimmed close, allowing the sunshine to enter freely. While green, the berries are thinned very severely at two different periods, consequently the berries are very large, perfect in shape, and highly flavored. Most of the plants that I have seen were remarkably healthy, but the red spider is common in the Guernsey vineries, and does much injury. Keeping the leaves abundantly showered with water, though it is but partially effective, is considered the only feasible remedy.

The farms in these Islands are, without exception, small, the dairy work generally managed by women, and the implements and mode of work simple, even primitive. Much of the work is also performed by women, who receive a franc or a franc and a half (29 or 30 cts.) per day. I saw no cattle market. The industry for which the Islands are specially noted abroad—cattle breeding, is mostly controlled by an agent in England, who takes orders from foreign stock fanciers, which he refers to local dealers in the Islands who are good judges of cattle. In the Channel Islands, one hears little of "Alderney" cows; Jerseys and Guernseys are the two standards, and they differ widely in their characteristics. The Jerseys resemble the cattle of Brittany, from which they are said to have been bred. They are small, symmetrical, and with graceful proportions; they have deer-like heads, and are generally mouse-colored, with black points, and always black snouts. Alderney has given its name to a breed of cattle, but comparatively few are exported. The Guernseys are said to have been bred up from the Alder-

phrases as "the old cow," or "the big cow," or "the last calf." Some of the prize Guernseys give 20, 24, and even 28 quarts of milk per day. In Guernsey, during summer, the cows are generally milked at morning, noon, and night. The milking is usually done by women. No calf is allowed to be sent from Sark to the neighboring islands without a certificate from the Seigneur (the Lord of the Manor), giving a permit, and stating the animal's pedigree, nor from the other islands without a similar document from the proper authorities.

"La Grande Charrue" (the Great Plow), is an institution in Guernsey. It is used for deep plowing, and is large and clumsy. Several farmers club together to use it—the team being made up of all the oxen and horses which the party can muster. The Great Plow is frequently honored with a team of four oxen and six or eight horses, or two oxen and ten or twelve horses, making quite an imposing turnout. After each day's plowing, the farmers who have taken part, hold a festival in the evening. Some of the small plows in common use are awkward in the extreme, resembling one of our ordinary one-horse plows; but, between it and the team of two horses, a low-wheeled carriage-part with pole is introduced, by which means the plow is removed far from the horses, half of their force being expended in lifting the carriage, which is below the line of traction; and were the strength of the team sufficient, I should expect to see the two wheels dangling in the air
Sark, July 15th, 1878. G. W. W. H

Hints for Work.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

Wheat and Rye.—Sowing the fall crops is the principal work of this month. It is useless to expect a good harvest unless the sowing of the seed is well done. There are several points to be studied:

The Fitting of the Soil is of the greatest importance. Wheat requires a fine mellow soil for the seed, and a light soil to be well compacted about the sowed grains. If any vacant places are left, as would be were the soil cloddy, the rootlets being exposed to air, will dry and perish. Therefore, after plowing, cultivate, or harrow repeatedly until all the clods are made fine.

The Surface Soil may be lumpy and somewhat rough, but the lumps should not be so large as to prevent the spires of wheat reaching the surface.

The Roller Should be Used immediately after the plow, to break up the lumps; then the cultivator and harrow will finish the work. This is the proper use of the roller. Its misuse is to roll the ground after the seed has been sown, thus leaving the surface packed down close and solid, in which state it will crust over after the first shower.

An Out or Barley Stubble should be well cultivated to destroy the sprouted seed which has been shelled in harvesting. We have heard it said that this volunteer growth protects the sown crop, which is a great mistake: it is really weeds, and crowds the young wheat or rye, prevents it from occupying the ground, and seriously injures it.

The Young Plant Should be Well Fed.—A weak plant will fail unless it has plenty of the right kind of food, and in such a condition as to be readily absorbed, digested, and assimilated. Thoroughly decomposed stable manure furnishes such food, and is a good stand-by for the entire growth of the crop. Properly prepared fertilizers—rich in nitrates (containing nitrogen) of potash or soda, and especially in soluble phosphoric acid, which is known to have a remarkable effect on the development of the young rootlets—may be used with safety and comparative certainty.

The Hessian Fly has done much damage, especially to barley. The spring brood seems to have been the most injurious. Late sowing, that is after the 10th to the 15th of September, will tend to prevent the effective deposit of eggs, and thus greatly lessen the number and vigor of the spring brood. Although by forcing the early sown wheat to a strong growth, it can be secured against the fly, yet we thereby furnish breeding places for insects whose progeny will attack the oats, barley, and wheat next spring.

Selecting Seed.—When it is inconvenient to attend to the selection of good seed, it is profitable to pay double or treble the market price for grain to a farmer who will take pains to grow nice, clean seed of the best varieties, than for a farmer to go to his own bin and take the seed as it comes, good and poor, with many foul seeds in it. A farmer who sows poor seed may save a dollar per acre, but he will lose ten for every one saved.

Cultivating the Fall-sown Crops.—It will be found decidedly beneficial to use a sloping-tooth barrow soon after sowing, and before the spire shows above ground, and again as soon as it has become well rooted. A harrow of the kind referred to was described in the *American Agriculturist* for August. After having tested this harrow, we find it to do excellent work with both sloping and straight teeth. It is light and passes easily over the loose ground, disturbing only the surface and killing only the shallow-rooted weeds, leaving the wheat uninjured. The loosening of the soil benefits the wheat, and prepares the ground for the timothy seed.

Harrowing Disturbs the Hessian Fly.—Doubtless this is because the wheat is pushed forward by the stirring of the soil, and many maggots are certainly destroyed.

Steeping the Seed.—For at least the partial preven-

tion of rust and smut in wheat the seed should be steeped in a strong solution of common salt, or in a solution of 4 ounces of sulphate of copper (blue vitriol, or copperas) in a gallon of water, for one hour. The seed is then drained and sprinkled with dry lime, when it may be sown immediately.

Water Furrows.—When all else is done, make the necessary water furrows at once. There may come a heavy rain the next day and do damage. Disperse the water into several channels, rather than permit it to collect in one or two. When the field is in grass, these water furrows will be useful in spreading the rain more evenly over the field.

Seeding to Grass.—It is a good practice on fertile soil to sow grass-seed two weeks after the wheat is put in. Thrifty growing timothy keeps the wheat back, as proved the past season on the writer's field. Other farmers corroborate this experience.

Sowing Right and Left.—After waiting two weeks for a still day the past spring to sow clover, the writer tried sowing with the right and left hand alternately, and it answered well. The method is this: With the wind blowing from the right over to the left, cast with the right hand; in returning, step seven or eight paces towards the wind, and cast with the left hand. There will be then no doubled places, and no streaks missed. To get the method, practise with light-colored sand, or chaff.

Root Crops.—Where mangels or ruta-bagas are crowded, pull the superfluous roots for the cows. The fresh feed will be useful, and those remaining will occupy the vacant space, and make a better growth by the thinning. White turnips may yet be sown if the land is rich, or made so. A vacant potato stubble treated with 250 lbs. of fine bone-dust per acre, will give a vigorous growth of turnips.

Buckwheat should be cut before frost. If a light frost kills the tops, it may be cut at once. Cut with a cradle or a reaper, while the dew is on, early in the morning, otherwise the grain will shell badly. Leave it in the swath until the straw is dry, then rake into gavels, which, without binding, set into small stocks, where they will dry in a day or two of bright, breezy weather. Then draw the crop to the barn in racks upon which barn sheets or blankets are spread, to catch the shelled grain, and thrash at once. If a machine is used, the concave should be removed and a piece of plank substituted, or the teeth will break the grain. When thrashed it should be cleaned immediately, and carefully stored, as it is apt to heat.

Late Potatoes.—As a measure of precaution for next season, every potato-beetle that can be found should be destroyed. When the leaves are eaten from potato vines, the growth of the whole plant stops; if new leaves start, it is at the expense of the tubers. So, kill the beetles, and increase the crop.

Corn.—As soon as the grain is glazed, corn should be cut, if the stalks are to be saved. Frost greatly injures the fodder, and reduces its feeding value. Before cutting, the seed for next year should be selected, taking ears from stalks that have borne two or more good ones. The tops of the selected stalks may be broken down, to mark them, and when the crop is cut, left standing until the ears are perfectly ripe, then they should be gathered, and stored in a dry, cool place. Such selections of seed will tell well in the next crop.

Weeds.—A great number of weeds are now maturing seeds; to permit this is simply to make trouble and expense, in years to come. Every weed about fence-rows, in fields, or about barns, and in nooks and corners, should be cut at once, and burned. By persevering in this way for a few years, a farm may be cleared of these fertility thieves.

Live Stock.—For hints about the management of farm animals refer to the August *American Agriculturist*. We will only add that, as cold weather is approaching, any falling off in condition should be guarded against. Extra feed may be given this month to young animals, with profit.

Sundry Matters.—This is the usual season for renewing insurances, and it ought not to be overlooked. The farm buildings, tools, and crops, should be secured so that in case of fire all will not be lost. . . . Preparations should be made for storing the

root crops; a substantial, permanent root house will always repay its cost, and a good one may be made very cheaply. . . . All the harvesting implements and machines should be cleaned and oiled—both wood-work and iron—and stored in a dry, covered place. To remove rust, use crude petroleum, then brush over linseed oil. Petroleum is a good preserver of wood. . . . Chicken coops and other "traps" put away until next season, in an outhouse, or shed. . . . Clean up all rubbish about yards and buildings, and remove to manure heaps—having all possible materials for compost gathered and utilized. . . . The sum of the small things which may be done with economy now that leisure offers opportunity, will be considerable. . . . Do not overlook the Fairs, and make a business of attending as many as possible, with observant eyes to things of interest and utility.

Notes for the Orchard and Garden.

A few months ago we suggested that it was a profitable use of time for cultivators to visit one another—to make excursions not only for pleasure but instruction. Equally, if not more, profitable will it be to visit a central point where the cultivators of a wide district have brought together the results of their season's labors for exhibition and comparison. This is what we find, or should find, at the various fairs, and these should be visited, as a matter of duty by every one, whether his orchard or garden be large or small. Visit the local Fair by all means, whether it be Town or County, and as many more as time and means allow.—"But these local fairs have but little interest."—Then make them interesting, and begin now to set about insuring a good exhibition of orchard and garden products. Some one in such matters must be a leader or agitator. Many fail to exhibit, because they did not think of it. See that your neighbors have not this excuse. Others would exhibit if they thought any one else would.—Tell such that you will exhibit if they will. Still others can be stirred up by a spirit of rivalry. Send word to such that you intend to beat them on grapes, turnips, or whatever the special hobby may be. It is astonishing how much one person, by a few timely words, can make the Horticultural Department of a fair a success. Who can better speak these words than the readers of the *American Agriculturist*? Do not refrain from exhibiting because you fear that some one else has better. Show the best you have, and if another has better of the kind, learn how he produces it. No matter if you are a Vanderbilt in wealth, and the premium awarded you is only 50c., take the money. This declining premiums by wealthy or well-to-do persons, touches the pride of those in humble condition, and they stay away. We have known a flourishing society nearly ruined by this, as it drove away the mechanics and others with small gardens. Wealthy persons do well when they make presents in cash to such societies, but they should always take their premiums. What ever is shown, let it be arranged to appear at its best. There are neat and slovenly ways of showing cabbages. Go to the fairs by all means, but go with something to exhibit, and be sure to take wife and children besides.

Orchard and Nursery.

In these notes on work are included answers to many correspondents, though this is seldom stated. Just now, as in past years, many ask about

Fall Planting.—The answer will depend much upon the locality of the inquirer. Other things being equal, the better condition of the soil, the greater comfort in working, insuring better planting, and the less pressing character of other work are all in favor of fall planting. Besides these, the trees having become established in the soil, start much earlier in spring, and are thus better prepared to resist the summer drouths than those set in spring. In far northern localities, in which there is but a brief period between the time when trees can be taken up, and the setting in of winter, spring planting is preferable, but where there are some weeks of autumn weather, it is better to

plant all but the stone fruits in autumn. In autumn planting it is well to make

A *Mound of Earth* around the base of each tree, from 10 to 15 inches above the general level. This serves to keep water from settling at the roots, and protects them from frost, helps to keep away mice, and serves as a stay or support for the tree in a much better manner than staking. The earlier trees are planted, after they have completed their growth and ripened the wood, the better.

Stripping the Leaves from nursery trees is regarded by many as improper, but if done at the right time there is no objection to it. When the leaves have done their work they are of no further use to the tree, and will fall in a heavy storm or with the first frost, and no more injury will result from stripping them off by hand than if they were left to be removed by natural agents, provided it be done when they are fully mature and prepared to fall. Stripping, properly done, allows the trees to be set out some weeks earlier than otherwise, in the fall. If left on, the trees would be difficult to pack; there would be danger of heating in the package, and if the tree were planted with the leaves on, they would carry on an evaporation that would greatly injure if it did not kill it. See hints on

Gathering and Marketing Fruit in last and previous months' Notes. Windfalls should not be wasted; they may be used for vinegar, for drying, or be fed to the pigs. Those who have large orchards find it profitable to provide a hand-press to treat windfalls as they occur, long before the general pressing, and materially increase the amount of vinegar.

Propagating.—Budding may be continued so long as the stocks are in growing condition; cut the ties of those buds that have taken. Collect peach and plum stones, and keep in sand until sown.

The Fruit Garden.

The reasons given for fall planting in the orchard, hold with the hardy small fruits and dwarf trees in the garden.

Strawberries.—Keep the beds entirely free from weeds, and remove all runners not needed. Planting was discussed last month, and an article giving useful hints will be found on another page.

Blackberries and Raspberries push their growth so early in spring, that fall planting is especially desirable for them. If not already shortened as directed last month, do it now. If it is desired to propagate *Black caps*, and other varieties that root from the tips, branches should be left uncut for the purpose; while they often take root without help, it is well to make sure by placing earth on the ends of the canes, to hold them in place.

Currants and Gooseberries may be pruned when the leaves have fallen, or will drop at a slight touch. Cuttings of this year's growth should be set at that time; make them 4 to 6 inches long, and set 4 inches apart in rows, with one end above the surface. Cuttings set this month, or early next, will usually be well rooted by winter.

Grapes.—In gathering, use scissors made for the purpose, which hold the bunch after it is severed, and avoid the necessity of handling, which, by removing the bloom, greatly injures their appearance and consequently the sale. Gather in trays or shallow boxes and keep in a cool, airy room for a few days, until the skin toughens somewhat.

Packing Grapes.—For immediate sale, or later to keep, wooden boxes of thin stuff, to hold 3 or 5 lbs. are preferred, though some growers use paper boxes. The bottom of the box is removed, and the grapes laid in, handling only by the stems, and enough put in to make it necessary to use slight pressure to bring the bottom to its place—which the curing or exposure, by toughening the skins, makes possible without cracking the fruit. See last month on mildew.

Pears need careful watching that they may be picked as soon as they mature; with some varieties, a delay of a few days will cause loss by decay at the core. Whenever the stem of the fruit parts readily from the branch, the pear should be picked, no matter how hard, and ripened in the house. Select specimens are sent to market in shallow

boxes holding but a single layer, each pear wrapped in white or colored tissue paper. Pruning to bring the tree into proper shape may be done now.

Kitchen and Market Garden.

Now that the cool nights have come, the late crops will be making a rapid growth not possible when both nights and days were hot. But cool nights are equally favorable to certain weeds, and there can be no relaxation of vigilance with these.

Clear up as you go.—When a crop, large or small, is taken off, clear up at once the refuse, and if the land is not needed for any crop, keep the weeds down by running the cultivator over it whenever that is used among the crops.

Cold Frame Plants are to be provided for. Those who are only used to the old fashioned way of gardening, which began with spring and ended with fall, do not understand that the earliest cabbages, lettuce, etc., are from seeds sown the fall before, the plants kept through the winter in cold frames, and set out in early spring. There is nothing about this that can not be done by any farmer or other person who will take the needed pains. We will describe the frame in due time; the seed for the plants must be sown this month. In order to have them of the proper size, gardeners, about New York, make two sowings, on the 10th and 15th of this month. Farther North the sowing is earlier, and in more Southern localities, later. The seeds of the Early Cabbages, Cauliflowers, and Lettuce, are sown in well prepared seed beds, and cared for the same as when sown in spring.

In *Virginia and Southward*, cold frames are not needed, but the plants are protected by ridges as will be described another month; the seeds for these, are sown the later part of this month, or early next, according to locality.

Celery should be making a good growth, which should be favored by frequent stirring the soil. If early celery is needed, some of the most forward may be straightened up, having the earth drawn to it with the hand; in about a week it is banked up with earth to half its height; and in another week banked again. It should be used as soon as blanched (which requires 10 days or so), as it soon becomes hollow if earthed up while in the growing state.

Corn.—As fast as the ears are taken from a planting, cut up the stalks to cure, if not fed out at once. During its abundance, dry a supply for winter; see note on page 287, last month, on preserving with Tartaric Acid.

Borecole, Kale, or in the New York market "Sprouts," is sown early this month. It is merely a kind of cabbage that does not make a head. Some varieties are quite ornamental, having handsomely curled and fringed leaves; sow the seeds in rows 15 inches apart; thin to six or eight inches, and keep clear of weeds until winter, when it is to be covered with straw, and may be used in spring.

Spinach for next spring is sown in the climate of New York, between the first and middle of the month. Sow in drills 15 inches apart, and keep clean; thin to 6 or 8 inches, using the thinnings.

Corn Salad is treated the same as Spinach, and is used in spring, mainly by Europeans.

Sweet Potatoes.—Prevent the vines from taking root by moving them occasionally.

Turnips.—The flat kind may be sown; Rep-top Strap-leaved is best, and will usually make a good crop, if sown as late as the middle of the month.

Melons.—Remove all that are not likely to ripen; the small musk melons may be used for "Mangoes," or stuffed pickles, if desired.

Shallots.—A hardy onion, which is ready for use in early spring, may be set, using the small bulbs.

Seeds.—If seeds are saved, they should never be from the leavings of a crop, but the finest and earliest plants or fruits selected in advance, and so marked that they will not be taken for use. If several varieties of melons, squashes, and others of the family, of corn, etc., are grown in a small garden, it is of little use to save their seeds, as they will be so mixed that only mongrels will result.

Radishes.—Those who like radishes in winter,

may sow the Chinese Rose-colored Winter, and treat and keep it the same as turnips.

Et Cetera.—Cucumbers, Martynias, Green Tomatoes, String Beans, etc., should be gathered while young and tender, and salted as stated on page 345.... Make Catsup while Tomatoes are plenty.... Use ripe Cucumbers for Cucumber Catsup. They may be peeled, sliced, dipped in batter and fried like egg plant.... Lastly, weeds.

Flower Garden and Lawn.

Now that the hottest days are over, an increased growth of grass will require a more frequent use of the mower. On new lawns the "Finger" or "Crab-grass" (*Panicum sanguinale*), is often abundant, especially the first year; fortunately it is only an annual, and if kept from seeding it will give but little trouble hereafter.

New Lawns may be made; grass sown this month, or, in the warmer States, next month, usually gives good results; and where the season is favorable for it to get well established before growth ceases, fall sowing is to be preferred to spring.

White Grub in Lawns.—A friend near Boston, whose extensive lawns have been models of excellence, writes that the white grub has been so destructive that some acres of turf are destroyed, the roots being eaten off just at the surface, so that the grass may be rolled up like a carpet. We have known of similar trouble, but not on so extensive a scale. The work is done so thoroughly that there are not roots enough left to allow the grass to recover if the turf were rolled, to bring it in close contact with the soil, and kept moist by watering, for which he has ample facilities, and there was nothing to be done but to make the lawn anew.

Is the Grub increasing in numbers? is a serious question for cultivators of all kinds, for there are but few plants, including young trees, that are not attacked by it. If it is not on the increase, it is noticed more closely, as we hear more of it of late than in former years. It is, as most readers know, the larva of the May or Dor-bug, and lives three years in the ground. As its presence is not suspected until the mischief is done, we can only make effective war against it in the perfect or beetle state. When discovered in large numbers on trees, the beetles should be caught by nets or otherwise, and as they are readily attracted by light, traps with a lamp for a "bait" must be devised.

Herbaceous Perennials.—For many of these, fall is the best season for transplanting; a few, like the Pæony, will not bloom the same year if moved in spring, hence these must always be transplanted now, unless we would lose a season of bloom. All the early bloomers, if set in the fall, will become well established and flower well next spring.

Bedding Plants.—Geraniums and such plants should now be at their best. If a stock is to be kept over winter, make cuttings for the purpose.

Chrysanthemums.—Those wanted to flower indoors, should be potted when the buds show, and shaded for a few days until they recover. Provide the tall growers with stakes, and keep them tied up, else they will be broken by storms.

Cannas.—Some of these are as desirable for their flowers as for their foliage; prolong the bloom by cutting away the stalks as soon as the flowers fade, unless seeds are wanted.

Dahlias need careful tying, and the larger branches may need separate stakes; the stems break readily; the flowers are heavy, especially when wet, and unless well cared for, they will be wrecked just when they should be most showy.

Ornamental Trees and Shrubs may often be advantageously transplanted in autumn, for the reasons mentioned under Orchard. Many prefer this season for the removal of Evergreens; success with these depends quite as much upon *how* as upon *when* it is done, the greatest care to prevent drying of the roots being essential at any season.

Greenhouse and Window Plants.

All plants in pots should be in the condition of an army waiting orders—ready for a move at any

minute." If houses and all their belongings are not in readiness, there is now no time to be lost.

Soils, Pots, and whatever other materials are likely to be needed, should be at hand under cover. In bringing in plants it is best to do it before a cool spell makes it necessary, as they can be examined and cleaned of insects if need be. Begin with the most tender, and bring them in gradually. House plants should not go to their quarters in the living-room at once, but be placed in a room where the windows can be left open all night, if need be, and thus gradually accustom them to confinement.

Seeds of Annuals for winter bloom may be sown now, and other sowings made later; Candytuft, Sweet Alyssum and Mignonette, are always in demand for cut flowers.

Hanging Baskets may be filled and furnished, and kept on the veranda until time to take them in.

Plants in open ground, such as Carnations, Tea and other roses, and others, expected to flower in winter, should be taken up and potted, and kept in a shady place until they recover.

Slight Frosts sometimes occur before the plants can be taken in; these may be prevented from doing damage to even the very tender plants by covering them with a sheet; even a few newspapers over the plants so secured that they will not be blown away, will answer the purpose.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our daily record during the year, show at a glance the transactions for the month ending Aug. 12th, 1878, and for the corresponding period last year:

1. TRANSACTIONS AT THE NEW YORK MARKETS.

RECEIPTS.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.
27 d's this m'th	1,061,000	4,447,000	4,381,000	251,000	294,000	1,213,000
25 d's last m'th	1,032,000	4,904,000	3,992,000	490,000	261,000	1,137,000

SALES.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.
27 d's this m'th	1,048,000	6,259,000	6,411,000	437,000	—	1,507,000
25 d's last m'th	1,046,000	6,318,000	5,151,000	450,000	93,000	1,956,000

2. Comparison with same period at this time last year.

RECEIPTS.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.
27 days 1878.	361,000	4,447,000	4,381,000	251,000	294,000	1,213,000
27 days 1877.	321,000	2,476,000	2,931,000	61,000	206,000	1,042,000

3. Exports from New York, Jan. 1, to Aug. 12.

Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.	Peas.
bbls.	bush.	bush.	bush.	bush.	bush.	bush.
77,159,205	27,101,173	18,239,911	2,561,907	1,515,149	2,086,051	206,112
77,159,205	27,101,173	18,239,911	2,561,907	1,515,149	2,086,051	206,112

4. Stock of grain in store at New York.

	bbls.	bush.	bush.	bush.	bush.	bush.	bush.
1878	3,100	9,850,000	10,114,000	735,000	304,000	2,321,000	197,000
1877	3,100	1,534,700	8,385,100	192,000	389,700	90,300	277,500
1876	13,700	7,997,900	2,665,000	327,000	114,500	1,091,200	355,500
1875	27,200	7,504,600	1,932,200	68,700	—	1,793,200	456,500
1874	35,100	11,590,000	9,795,300	189,800	71,000	1,216,700	356,200

5. Tide-water Receipts at Albany, from opening of navigation to Aug. 7.

Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.	Malt.
bush.	bush.	bush.	bush.	bush.	bush.	bush.
1878.	3,400	8,956,000	10,114,000	75,000	34,000	2,221,000

Gold has been up to 100%, and down to 100%, closing Aug. 12, at 100%, as against 100% on July 13; 100% on June 13; 100% on May 13; 100% on April 17; 100% on Jan. 12; 100% on Dec. 12; 100% on November 12; 100% on October 12; and 100% on July 12, 1877. An active business has been reported in Breadstuffs, mainly for home use, and export, but to an important extent also on speculative account. Prices have fluctuated frequently and widely, influenced chiefly by the unfavorable tenor of the domestic crop and weather reports, and the use made of these to promote speculative interests, especially in the Milwaukee and Chicago markets, where Spring Wheat has been ruling much higher, relatively, than on the seaboard, thus impeding the outward movement. Receipts of Grain, however, have been recently on the increase at the more prominent points of accumulation in the interior—notably so of new crop Winter—and more liberal

also at this port. Toward the close, the general market here has shown more firmness, with a rather confident inquiry for shipment, chiefly for Winter Wheat, steamer and sailing vessels grades of Corn, prime Rye, and No. 2 Chicago Oats. Home trade requirements have been fair, though, as a rule, not very urgent. Spring Wheat Flour has been advanced sharply, during the month, closing strong in price, on much lighter offerings, particularly of the Minnesota Extras. Provisions have been in more demand, and prices have been generally quoted higher. Wool has been more freely purchased at firmer prices, holders of desirable qualities of domestic showing much more confidence. Cotton has been quoted rather dearer, on a livelier business. Seeds have been attracting more attention; and prime rough Flaxseed has been purchased to an important aggregate for August and early September deliveries, at \$1.35-\$1.40, closing at \$1.40 per bush. Hay, Straw, and Hops have been quiet at irregular prices. Naval Stores and Petroleum, less freely dealt in, and quoted weaker in prices. Groceries, fairly active; Coffee, firmer; Sugars and Molasses, lower. Ocean Freighters have been more active, especially in the Grain and Petroleum interests, opening higher, but closing weaker. Grain rates by steam to Liverpool closed Aug. 12th at 7 1/2 d. (about 15 cents) per bushel; Glasgow, 6 1/2 d.; London, 6 1/2 d.; Bristol, 7 d.; Hull, 8 d.; the Continent, 8 d. 9 1/2 d. by rail to Liverpool, 6 1/2 d.; London, 6 1/2 d. per bush. Flour to Liverpool, by steam, 2s. 6d. (about 60 cents per bbl.); by rail at 2s.; London, 2s. 3d., and by steam, 2s. 6d.; Bristol, by steam, 2s. 9d. @ 3s., and rail, 2s. 4 1/2 d. @ 2s. 6d. per bbl. Provisions by steam to Liverpool, 30s. @ 15s. per ton. Butter, in refrigerators, 125s. Cotton, by rail, 7 1/2 d., and steam, 1 1/2 d. per lb. Grain, by rail, for Cork and orders, at 5s. 9d. @ 6s. per quarter (8 bushels), and to Continental ports, 5s. 4 1/2 d. @ 5s. 9d.; and from Philadelphia for Cork and orders, 6s. 3d. from Baltimore for Cork and orders, 6s. 3d. @ 6s. 6d., and Philadelphia for Lisbon, Wheat in bags, at 16 1/2 c. per bush.

CURRENT WHOLESALE PRICES.

Beesves.—The market has been a poor one the past month. The heavy receipts, and the so-called "under consumption" together, brought prices down to the low average of 8 1/2 c.; the fall being most on poor stock, of which many lots have been carried over from week to week wanting buyers. To make things worse, the foreign trade has fallen off, one or two shippers having suspended operations, and others, looking in vain for profits, are reducing their business. As the month neared the close receipts fell off—the last week nearly one-third, and prices recovered a little. Still the tone of the market was bad, and with everything in favor of sellers but a small advance was made. For once, however, the pens were left empty, and stocks were cleared off, and that was a gain. Prices at the close were 10 1/2 c. per lb for extra steers of 1,350 lbs., estimated 57 lbs. to the 100; 10c. per lb for 1,293 lb steers, same estimate; 9 1/2 c. per lb for 1,250 lbs., estimated 56 lbs. to the 100; 8 1/2 c. per lb for lighter cattle, and 6 1/2 c. per lb for Texans of 55 lbs. to the 100. A lot of bulls were sold at \$2.60 per 100 lbs., live weight. Dressed beef sold at 6c. @ 8c. per lb for natives, and 4c. @ 6c. per lb for Texans.

WEEK ENDING	Range.	Large Sales.	Aver.
July 22.....	7 @ 10 1/2 c.	8 1/2 @ 9 c.	9 c.
July 29.....	7 1/2 @ 10 1/2 c.	8 1/2 @ 9 c.	9 1/2 c.
Aug. 5.....	6 1/2 @ 10 1/2 c.	8 @ 9 c.	8 1/2 c.
Aug. 12.....	6 1/2 @ 10 1/2 c.	8 @ 9 c.	9 c.

Cows.—After a struggle to maintain prices, dealers have been forced to give way, and the best cows have sold for \$60 @ \$65. Ordinary milkers sell for \$50 to \$55. Stock is coming in too freely for the light demand.

Calves.—The trade in veals has been dull, but prices have held their own, and prime veals sold for 6 1/2 c. per lb, with 7c. for extra. Good to fair brought 5 1/2 c. @ 6c., and grass and buttermilk calves at 3 1/2 c. @ 4 1/2 c. per lb.

Sheep and Lambs.—Buyers have done what they pleased in the sheep market; no reasonable offer has been refused. The market closed more depressed than at the beginning of the month. The dead meat market is equally unsatisfactory. Prime heavy sheep were taken last week at 4 1/2 c. @ 5c. per lb for export; fair to good sold for 3 1/2 c. @ 4c. per lb live weight. Lambs brought \$4.25 @ \$5 per 100 lbs. Stock ewes brought \$4 per 100 lbs.

Swine have been steady through the month, closing at 4 1/2 c. per lb for live and 5 1/2 c. @ 6c. per lb for dressed. Market pigs brought 6 1/2 c. per lb.

The Horse Market.—The horse market has been extremely dull. There is no sale for green animals this hot weather, as they can not stand the unusual work on the hot city streets. Old veterans, which are daily dying off, have their places filled by younger animals, but no purchases are made that can be avoided. In the week ending Aug. 12th, 65 head were exported, and 2 full-blood Norman stallions, 2 mares, and a colt, were imported through Robt. Stoddard's bonded stables. A valuable trotting horse, valued at \$9,000, was also imported the same week. In a few weeks the usual fall demand will be looked for, and business may be more active. No useful quotations can be given at present.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

A Woman Farmer at Valley Springs, Dakota, who deserves success, wrote to Messrs. B. K. Bliss & Sons, in regard to their wheat prizes, as follows: "It did not occur to me in writing to you yesterday, that you might think it singular that a woman should write you for seed in order to compete with men for a prize. To convince you that I am not incompetent to try, I will mention a few items of the work I have accomplished already: We lost all we had, by fire, and came West, to make a new home. As soon as a portion of the claim could be broken up and made suitable, I commenced putting out forest trees and small fruits, as far as I could command the means to purchase. The first year I rode nine miles on horseback to the nearest timber; took up, brought home, and set out four hundred forest trees. The next year I set out four hundred feet of willow hedge, besides currants, blackberries, strawberries, and raspberries; the next year a large lot of asparagus, pie-plant, one hundred raspberries, and eighty dwarf cherry trees. This year I shall complete seven hundred feet of willow hedge, set one hundred raspberries, two hundred strawberries, and make a large garden, and flower beds, besides doing my own housework for four persons. Won't you please permit me to try for a prize?" She was placed in the list of competitors, and we hope to record her as first prize winner.

Manual of the Apiary, by A. J. Cook, Professor of Entomology in the Mich. Ag'l. College. The author is known to us as an earnest student, and excellent observer, and has in the present work given the latest views as to the physiology of the bee, and the recent improvements in bee-keeping. Like a true naturalist, he does not assume to know everything, but all through the work gives credit to other authors and reference to other works, where particular topics are treated more in detail. The work, 285 pages, abundantly illustrated, is sent from this office, postpaid, for \$1.25.

How Strawberries are Sold in Belgium.—Our correspondent "G. W. W. H." writes from Frankfurt: In travelling through Belgium in June, strawberries are brought to the car windows at every station—luscious great berries, some red, some white, often as large as a pullet's egg, and temptingly displayed in shallow baskets, made of split willow, in the form given in the engraving. Baskets of this shape seem to us well deserving of introduction in America. The construction is simple, strong, and inexpensive. A single willow with the handle and middle support of the bottom; a second with bent

to a circle forms the rim; and four others, *i. e.*, two on either side between the middle piece and rim, complete the foundation into which thin strips are braided. The depth is only a quarter inch, diameter three inches. On the bottom are a few fresh grape leaves on which are placed the berries, nearly all of them exposed to view.

"Ferns in Their Homes, and Ours," is the attractive title of a work on Ferns, and their Culture, by John Robinson, Esq., of Salem, Mass. If the welcome accorded to a work is in proportion to the need for it, this should meet with a large and rapid sale, for there is no special work for which there have been so many inquiries as for one on ferns. It is not easy to conceive how this demand could be more acceptably met than by the book in question. While those who cultivate ferns

may not care to give much study to their botanical characters, every intelligent person will wish to know what constitutes a Fern, and how it differs from other plants, all this is admirably told in the chapter on "The Life of a Fern." Abundant references are given to those who would study ferns botanically, and an excellent sketch of the literature of the subject is given. Having long known of the author as a thorough student and successful cultivator of these plants, we were prepared to find in the practical portions of his book the results of experience in the culture of ferns, under glass and out of doors. The work, presented in the neatest possible form, and well illustrated, is creditable to the publishers, the Naturalist's Agency, Salem, Mass. Sent postpaid by the Orange Judd Company for the publishers' price, \$1.50.

A Shirt for 50 Cents—Seemed to us so improbable, that we ordered a dollar's worth of shirts to see what they could be like. Of course, finer shirts are made, but how even such shirts as these are made for so low a price, still remains a problem—we give it up.

Peaches by Mail.—Some six, or more, correspondents have notified us that they have sent specimens of peaches by mail, asking our opinion as to quality, earliness, etc. In no case, *save one*, have these specimens been received. In this single case the ruling is strange enough. The sender properly paid postage on the parcel, as third-class matter. The parcel came to us, marked 92c—letter-rate, the stamps put on by the sender ignored, and the package marked, "non-mailable."—How it could be "non-mailable," when it *was* mailed, and delivered at letter-rates—or why the post-stamps put on by the sender should go for nothing—he confiscated, as it were, are among those things that "no feller can find out." It may be that we shall some day have a postal law that both the people who use the mails and the Washington "powers" will understand alike—until then we must endure with what patience we may.

Artichokes for Hog-Food.—A circular from "E. F. Brockway," of Ainsworth, Iowa, offering Artichoke tubers for sale for planting, reminds us that this root is an excellent food for hogs, for which purpose it is now quite extensively grown in some sections; they are more nutritive than any ordinary vegetable, save the potato, and nearly equal that chief of vegetables. Under systematic culture they are easily grown, and yield large crops—even as high as 800 bushels per acre having been raised, and 1,500 to 2,000 bushels per acre yields are claimed in some instances. They are planted like potatoes, in spring, on light dry land, and cultivated the same as corn. Of course this is the plant known as "Jerusalem Artichoke," a variety of which is offered as the "Brazilian Artichoke."

The Best Lamp is what is commonly called the "German Student Lamp," or some one constructed on the same principle. These lamps are made in America better than elsewhere. Mr. Hinrichs says the proper name is "St. Germain." These have a reservoir of oil so arranged, that whenever the oil around the wick sinks so much as an eighth of an inch, a bubble of air enters the bottom of the reservoir and lets down more oil. A lamp flame is fed by oil ascending by capillary attraction through the wick. In the common lamp, as the oil burns away, it has further to rise, and feeds slower, and as the wicks are not uniform, and are often clogged, the light both diminishes and is unsteady. In the Student Lamp all this is obviated; there is a clear, steady light as long as the reservoir holds a spoonful of oil. Such lamps are vastly superior to the light of gas, which, owing to constantly varying pressure, is always unsteady, straining the eyes, even when it is not flickering. As to economy, our "family expense book" shows for the same quarter in the year, that after introducing the Student Lamp through the house, kitchen included, and using Pratt's Astral Oil, bought at the regular price, through the grocer, we had a better light at *one-tenth* the expense of gas. By the way, there is an important addition to the old ball-and-pin valve, in lamps constructed on the above principle. A cut-off is attached to the discharge tube at the base of the reservoir, which also has a catch at the side that not only stops the churning motion but also prevents its being lifted out until it is turned so as to close the discharge tube. After filling and replacing, a quarter turn opens the bottom. This arrangement is safer and more convenient, as it avoids the usual dripping or spilling of oil, and prevents any over-flowing of the wick.

Trimming Lamps—The Best Way, by far, is not to trim them at all. It is very difficult to cut the wick evenly all round, and any portion or point left higher than the rest, gives an irregular flame, if not smoke. All that is needed, is to remove the thoroughly charred portion at the top. Turn the wick up just enough to expose this part, and rub it off with a cloth or with soft paper; the top of the wick will then be even with the fire

line all round. To prevent soiling the lamp or table, the charred part can be pinched off mainly, giving it a final smoothing rub. The dark portion that will not rub off, is quite as good as the unburned parts, and will light more quickly. When impure oil is used, the wick becomes coated all through with dust or dirt; and when this accumulates so as to interfere with the ascent of the oil, a new wick is essential.

A Turnip Topping and Pulling Machine is extensively used in England, where the turnip is one of the principal crops grown on all stock farms. The increased acreage devoted to the crop in this country creates a demand for some simple machine for harvesting it. We reproduce an illustration from the "Agricultural Gazette" (Eng), of one known as "Hunter's Turnip-Topping and Tailing Machine," which is simple in construction, and said to be effective in operation, and is self-acting. "In a neat wrought-iron frame, two saws are fixed to guides, which run on the crown of the turnip, and prevent the saws from cutting or bleeding the root. The whole is hinged to the frame at one end, and fastened by means of a chain to the other, so that the cutting saws adapt themselves to the variously-sized roots. At the back end of the machine, and well clear of the saws, is a cast-steel concave blade or shear, which lifts the root

without cutting, so that by the use of this implement, a crop of turnips and sweeties can be lifted and topped with much despatch. It is also made double." We understand that the machine is not patented in this country, and it is so simple, that any good mechanic, by the aid of a blacksmith, ought to be able to make one.

Caponizing.—"F. E." Sussex Co., N. J. Young fowls cannot safely be caponized after they are 3 months old. When of 6 or 8 pounds weight there is more risk than when they weigh half that. Capons frequently weigh 10 to 16 pounds, and sell for much more than common fowls. For the price of the instruments write to H. H. Stoddard, Hartford, Conn. "Philadelphia dry picked" poultry doesn't come from that city, but from Bucks and Berks Counties, Pennsylvania, and other districts, for which the nearest market is Philadelphia.

Merino Rams.—"W. H. O.," Washington, D. C. It would not pay a breeder of prize Merinos to raise them for \$5 a head. That is about the mutton price for an ordinary native sheep. A good Merino ram cannot be raised for less than \$15 to \$50, according to the breeding value of the stock. The latter price is very moderate for an animal that will add a value of at least one dollar for each of the lambs he may sire—60 to 80, from 50 ewes each year. They can be procured of advertisers in this Journal.

"House Plans for Everybody," by S. B. Reed, Corona, L. I., N. Y. The House Plans which have formed a marked feature in the *American Agriculturist* for the past three volumes, have differed from most such plans in the fact that nearly every one has been subjected to the test of practice. They have not been the ideals of an architect, but represent houses that have actually been built. The work abounds in a great number of practical common-sense suggestions, convenient and useful devices, many of them original ones. Another most useful feature is the estimate of cost, down to the minutest details, so that one may calculate from the price of lumber at any given time or place, within a few dollars of the outlay required. These plans cover such a wide range as to style and cost, that they may be properly designated "for everybody," as the needs of those who can afford only a \$250 cottage are as carefully provided for as those who invest \$8,000 or more in a handsome mansion. There is not only this wide range of prices, but an equally wide variety in styles, and while none are overloaded with ornamentation, costly at first, and more costly to keep in repair, the pleasing aspect of the dwelling is regarded in even the humblest of the designs. The many persons, builders and others who have purchased bound volumes of the *American Agriculturist* solely for the sake of these plans, and all others who wish really practical designs for dwellings, arranged with a view to the comfort and convenience of those who are to live in them, will be glad to know that they have been reproduced in the form of a Book with the above title. The engravings, on the heavy tinted paper, with the careful printing

that can be given to a book, appear to much better advantage than they possibly could in the rapid presswork of the newspaper, and while they form a most useful, they make a really elegant book. There are 40 designs, each illustrated by a perspective view or elevation, and plans for each floor, besides numerous engravings to illustrate details of construction, when needed. All is made so plain by description and illustration, that any one of ordinary mechanical ability can build from any one of the designs. Being "for everybody," it is sent at the low price of \$1.50, postpaid.

Rates Reduced.—Our readers will see by an announcement on page 321, that there has been an essential reduction in the subscription rates of the *American Agriculturist*. This will, no doubt, greatly enlarge our circle of readers, and the editors will spare no effort to make the paper meet the wants of the whole family, however large it be.

"Talks on Manures."—This work, by Mr. Joseph Harris, which was announced some two months ago, will be ready for delivery by the time this reaches our readers. It was stated that one of its most valuable features was the presentation of the elaborate tables of the remarkable experiments at Rothamsted, England. The sole value of such tables consists in their accuracy. The composition and correction of these consumed so much time that it was not possible to produce the work at so early a day as was expected. However, a work on manures is, unlike one upon many other agricultural topics, seasonable at any time, and we feel sure that this will have a hearty welcome from the large circle of readers who have already known the author through his other writings. This is not especially a work on fertilizers, but on manures, in the widest and broadest sense of the term, and its teachings, while in accordance with the established facts in science, are divested as far as possible of technicalities and of all show of what the Deacon would call "scientific larnin," but are conveyed in that pleasant, colloquial manner which his "Walks and Talks," and "Talks on Crops" have made familiar to so many. Where pleasant reading and sound teaching are so happily combined as in the present work, it can not fail to be widely useful in its effects upon farm practice. Pages 354. Sent by mail for \$1.50.

"Winter Greeneries at Home."—Just as shorter days and cooler nights remind us that preparations for our "Winter Greeneries" must soon be made, here comes the needed work in the very nick of time, to tell what to do, and how to do it. The author, the Rev. E. A. Johnson, D.D., of Allegheny City, Pa., has not brought together all he knew, and all that he could find that any one else knew, in one promiscuous and confusing jumble, and called it "Window Gardening," but has given an account of his own "winter greeneries," and told it all so pleasantly and plainly, that they must be indulged who cannot follow in his steps to something like his success. "Attempt only what can be done well," is not enjoined anywhere in the work, that we recollect, but that is the idea that pervades it. There is nothing advised beyond the reach of those of moderate means, and whoever will follow his simple teachings may hope to attain a success approaching the author's own, as shown in the fine illustrations of his beautifully "embowered study." The title of the work conveys his method; green in the form of ivies and other climbers, green in the trailers and droopers, green from above, green at the sides, green in graceful ferns, and quaint forms, green—cheerful green of various shades make up his "winter greeneries." Following Nature, he establishes the ground work of green, and then, following the same excellent teacher, lights it up with bits of color, in the way of bloom, which are all the more effective for their setting of green. Then he does not thrust a whole florist's catalogue at one, but in his selection of "Winter Bloomers" judiciously points out the few plants that one may have in a living-room—for the greenery is to be for and with the household—and with any fair treatment give flowers in winter. Having been over much of the same ground in the management of house plants, we feel sure that the author is as safe a guide as he is a pleasant one. And we are glad that we have in "Winter Greeneries at Home" a work that will do much towards encouraging and increasing the culture of house plants, by showing the beginners how to begin. The work is handsomely illustrated, with views of the winter greeneries at home with the author, and engravings of the various ways and contrivances that his experience has suggested. While eminently practical, the work is handsome enough for a "gift book," and is sent by mail, postpaid, for \$1.

The Massachusetts' Horticultural Society deserves much credit. If it is one of the oldest societies of its kind, it is also the most active. It gives us its "Transactions" for the first half of the year 1878,

by the time the second half of the year has fairly begun. The essays read at the meetings, and the discussions to which they gave rise, are of interest, and that interest is not decreased by their prompt appearance in a neat and carefully prepared volume. Much credit is due to the present Secretary, Robt. Manning, Esq.

Sundry Humbugs.

If one fraud has been more thoroughly exposed than another, it is Clark & Co., "Claim Adjusters." We began to show their methods, under various aliases, last year, and there has been scarcely a month this year in which some new phase of their operations did not call for a new warning. Besides this, Clark & Co. have become so conspicuously notorious that the daily papers have taken them up, and if there is a concern that has been widely advertised—after a fashion—it is this. Yet Clark & Co. are good judges of human nature; they know that but few people, in proportion to

the whole number, read, and of those who do read, a very small proportion recollect what they have seen for any length of time; they also know that a large share of mankind feel flattered at being addressed personally, by letter, and if this letter contains a tempting bait, in which the hook is cleverly concealed, they stand a good chance to get some bites, so this remarkable firm of

CLARK & CO. STILL CONTINUE

to send out those nice letters asking, "Is this your signature?" and will continue so long as it pays, or until some one who finds that he has been wronged, will visit New York and enter a complaint. This is very unlikely to happen, as the letters are, as a general thing, sent to persons living at a great distance. It is very amusing to see how particular many are to request us to be sure to return Clark & Co.'s letter which they have sent for our inspection, while they know that they have invested in neither mining stock nor jewelry speculations, feel that there is just a possibility that something may come of it, and wish the documents returned. If these persons knew that we have received *bushels* of these Clark & Co. letters, they would not place much value on theirs. ... That remarkable

AMERICAN AND EUROPEAN SECRET SERVICE CO.

is not the Co. we should like to employ on any "secret service," as the managers, or whoever run the concern, do not know the members of their own force. Imagine the surprise of a business man, the head of a large agricultural implement house in Missouri at receiving such a communication as this:

"Dear Sir—As we consider you one of the best detectives on our force, we desire to publish your picture in our paper, and also give you a favorable notice, for which we will charge you only \$10—the actual cost of engraving, the notice being FREE. Write at once."

Then follow requests for photograph, biographical sketch, etc. No wonder our Missouri friend requests us to "warn the public of these frauds," which we have been doing for some months. The scheme seems too absurd to succeed, yet has no doubt trapped many.

THE VALUE OF ANY SECRET SERVICE

depends upon the skill of the agents, and the fact that they are *not known* to be agents or detectives. Yet this so-called Company has been appointing "detectives" right and left, the chief condition being that each shall subscribe to, and send \$3 for their paper—the rest being all promises. Now, they appeal to the vanity of their dupes in this picture dodge, and will no doubt get many a poor fellow's \$10—who has not sense to see that publishing the portrait of a "detective" is the greatest possible absurdity. ... Those chaps in Calais, Me., still send out letters informing the recipient how his name was obtained. "Returning from our mine,

WE MET A GENTLEMAN ON THE CARS

from your locality, and we asked him to give us the names of some persons who might take an interest in mining," etc. This accompanies a circular showing "How Fortunes are made in Mining," accompanied, of course, by offers of the stock itself, "if applied for at once." The number of times these people returned from the mines, and the number of "gentlemen" they met in the cars are beyond computation. Common-sense people

will ask: "If such fortunes are to be made in your mines, why don't you make them, and not spend time and money in writing and sending such transparent stuff as this 'gentlemen on the cars'?"

THIS SEMINOLE GOLD AND SILVER MINING COMPANY, whose proprietors are always meeting "a gentleman on the cars," is not very definitely located; the circular says it is one day's ride from the Union Pacific Railroad in Wyoming Territory. —The "Carbon County News" Rawlins, Wyoming, (see "N. Y. Tribune" Aug. 13, '78, p. 5), has very decided opinions as to this mining scheme, and others like it. We advise all who contemplate investing in these mining schemes to either visit the locality—if they can find it—or write to the above named journal for a copy giving its views of the mines. The Wyoming people complain that schemes like these interfere with the development of the real mineral riches of the Territory.

DO HUMBUGS, LIKE COMETS,

have their periods of reappearing? This would seem so from the fact that every now and then a very old one, that we had quite forgotten, comes around as new.

We infer from our letters that there is a revival of

THE TREE COTTON SPECULATION

in some of the Western States, as we receive inquiries as to its culture and yield, and how long after planting a crop may be expected. During the war, when cotton was at its highest, there was every inducement to raise cotton in the Northern States, and every thing that promised to be of value was tried. Some samples of "Hardy" and "Tree Cotton" were brought us by gentlemen who could have no motive for swindling, claiming that they could be profitably grown in all the Middle States, but these gentlemen were mistaken, and their well intended trials, like the numerous swindles to which they gave countenance, all alike ended in failure. We advise our inquiring friends to first try two or three plants, before they bother about the yield per acre.... The "Butter Compound" business in Massachusetts seems to be remarkably quiet, but we hear of another

BUTTER COMPOUND FROM OREGON,

the old Ohio concern, which we supposed dead long ago. A citizen of Oregon, who, misled by the claims and plausible offers of the "Company," took the agency, now sends us all the documents, agreements, etc., and asks us to publish the concern as

"THE GRANDEST HUMBUG OF THE AGE."

We have been publishing this as a humbug these many years, and are glad that there is one less "agent" for the sale of the vile stuff.... A friend in Seward Co., Neb., writes: "A great many persons here are investing in — & Co.'s (Wall Street)

"SO-CALLED COMBINATIONS,"

and begs us, if we have any more light upon the subject, to let it dawn on them. We have said in these columns all that can be said. We can not point out one single concern and say, these are frauds, but we can say, as the opinion of the best business men in Wall street, as well as out of it, that all these parties who send out tempting circulars, are in bad company, and that the business—even if honestly conducted—is full of such risks as no one of moderate means should run. It is really a game of chance, having all the fascinations of other such games, and the player is pretty sure to lose in the end. There are, in Nebraska, as elsewhere, certain persons who are on the lookout for a chance to acquire riches by some unusual means. Such persons, when they get a few dollars ahead, are not happy until they can get rid of them in some lottery, or some mining or Wall St. scheme, and the more extravagant the claims put forth by these, the more readily do such persons fall into the trap. Warnings are wasted upon such, and it is only those who can stop and think that we can hope to benefit.... An Arkansas subscriber complains that his neighborhood is

FLOODED WITH LOTTERY CIRCULARS,

and thinks it suspicious that the documents are mailed in New York City in a sealed envelope, to be answered at New Haven, Conn., while the lottery is to be drawn in Cuba. Our Arkansas friend doesn't know the "ways that are dark," taken to avoid the vigilance of the Post Office officials. But what are the New Haven officials about, that lottery tickets can be openly advertised from the City of Elms?....

SWINDLES UPON FARMERS,

especially in the way of introducing new implements, continue to be reported; these, a few years ago were more frequent in New England than elsewhere, but a case given in a recent "Ohio Farmer" shows that these chaps have taken the advice to "go West." It is the same old story. Two glib-tongued chaps call upon the farmer, and at once make friends. They find it a pity he should work so hard for a little profit, and show how he may essentially add to his income by taking the agency for their machine. They, after much talk, persuade him to sign a contract to act as their agent, and

depart. In a few weeks the farmer learns that there is a large lot of machinery awaiting him at the railroad depot, and he gets a notice from a neighboring bank that his note for a certain amount is due. In a case in Butler Co., Ohio, a farmer found that he had signed an order for "twenty Marsh's Improved Corn Shellers," when he supposed that he only agreed to act as their agent, and to receive a corn-sheller free. This and other cases of frequent occurrence add force to our injunction.

FARMERS, BE CAREFUL WHAT YOU SIGN!

It should be added that the real makers of the implement, Marsh & Co., knew nothing of the operations of the swindlers.... Recent readers of the *Humboldt column* can have little idea of the extent to which the

COUNTERFEIT OR "QUEER" MONEY

business was carried on 10 or 15 years ago. Those who have the back volumes, will find that we often warned our readers against 10 or 20 dealers each month. The whole thing, as explained in full in the former volumes of the *American Agriculturist*, affords a remarkable and curious chapter in the history of crime. Of late, we hear of these dealers but rarely, and they seem to be more cautious than formerly. The latest is from a chap in New York to a lawyer in Nebraska, informing him that he got his (the lawyer's) name, from the book of a former dealer, and that if he is in want of such money now, the writer will give him, "the name of a *bonafide* dealer from whom you can obtain the money of the *finest kind*." * * I make a small commission on goods sold to customers whom I find.... This is in quite strong contrast to the bold game played a few years ago, making appointments at obscure hotels, and threatening the one who receives the letter with death in case he betrays the writer. It is a satisfaction to know that we have done our share in breaking up this rascally crew.

MEDICAL MATTERS

appear to have succumbed to the "heated term," and but a single novelty, or rather old thing in a new shape, has turned up during the month. This is a pamphlet on

"ELECTRO-VOLTAIC AND MAGNETIC

Belts, Bands, and Appliances for Self Cure," which is one of those pernicious publications, ostensibly intended for the benefit of young men, but really calculated to work upon their imaginations and excite their fears; having convinced the unfortunate reader that he is in a bad way, he is ready for the assurance that his only hope lies in the application of this electric concern. Our views of these so-called electrical appliances were given a short time ago. In brief: electricity *may* be a useful agent, but it should be applied under the advice of a physician, who is *present* to examine and prescribe. Many of the electrical appliances, though they have a "scientific" look, are utterly useless, being at most a series of closed circuits, which pass no electricity into the body, and all the good they do is in acting upon the imagination of those using them.

Successful Strawberry Culture.

Mr. Eli Beard, of Rockland Co., N. Y., has been, and is remarkably successful with strawberries, and many who have seen his patch, have asked him for his method of culture. Finding it a task to reply to the applications, he has concluded that the most direct way of reaching everybody, is to have the account published in the *American Agriculturist*. Mr. B. writes:

"The plants are set in rows 20 inches apart, and 10 inches apart in the rows—the earlier in the spring the better—and cultivated in the usual way the first and second seasons. After the fruit has been gathered the second season, between the first and middle of July, the vines are cut close to the ground; new plants will appear soon after the cutting. In the following September, the old roots, which have become dead and are of a dark color, are removed from the vines, being careful not to disturb the new and living ones. Late in the fall, before the ground is frozen, cover the plants with from two to four inches of coarse littery manure. In the spring, after the ground becomes settled, remove the coarse manure from over the plants and fork it into the soil between the rows; cultivate, and remove the weeds from time to time, keeping the runners cut off and not allowing them to occupy the space between the rows. After the blossoms appear, mulch thoroughly. My plot is about 40 feet square; it was planted seven years ago. The above method of cultivation has been strictly observed; the product has increased every year up to the present, both as to quality and quantity. Two years ago we picked from the plot over 30 bushels; since then we have not been careful to measure or estimate the yield, but are confident that not less, but probably more fruit has been produced. After the second year, the vines run together, making a continuous solid row, which is from 4 to 6 inches wide on the ground."—[Mr. Beard's method is a modification of what is known to cultivators as the

"Matted Row" culture. He attributes his success to: 1st, clean culture and an abundance of manure. 2d, to cutting off the foliage after the fruit is gathered—an old method, about which cultivators do not agree. 3d, the removal of the "old roots," which we judge, from his description, are the under-ground stems of the plants, with the sort of bulb made by the hardened bases of the leaf-stalks. In this way he secures a thorough renewal of the plants each year, and by having highly enriched soil for the new plants, he gives them the best possible chance. Mr. B. says, that originally there were the Wilson, Green Prolific, and two others, the names of which are lost, but they are now thoroughly mixed.—Eds.]

Some Bee Notes for September.

BY L. C. ROOT, MOHAWK, N. Y.

In most localities, all surplus honey boxes should be removed from the hive before this date. The practice of leaving boxes upon the hive until late in the season, should be avoided, as they become soiled by so doing. All unfilled boxes should be removed as soon as the yield of honey is over, and packed away for the following season's use. Combs containing honey in partly filled boxes, may be taken out and the honey drawn from them with the extractor, and the combs used for guides in boxes next season. If single-comb boxes are used, the honey may be extracted without removing the combs.

MARKETING HONEY.—Where but a small amount of surplus honey is secured, it is usually best to dispose of it at a home market. It requires less attention in packing, and, as a rule, will bring a better price. Large quantities will necessarily be shipped to a city market. The provision of a proper package for transportation is essential. For box honey the shipping-case should hold from 10 to 25 lbs., and may be neatly made as follows.—The size will depend upon that of the boxes to be packed;

Fig. 1.—BOX FOR SHIPPING HONEY.

basswood lumber is most suitable: Cut two pieces, $\frac{3}{4}$ or $\frac{1}{2}$ in. thick, of proper dimensions, for the ends. At equal distances from the ends, and about one inch from one edge, cut a hole $\frac{1}{2}$ in. deep for a handle, as at *a*, figure 1. A top and bottom, and four strips $1\frac{1}{4}$ wide, an of $\frac{1}{4}$ or $\frac{3}{8}$ in. thickness, according to the size of the crate, constitute the remaining material of the case. Nail together, as shown in engraving. Before packing, boxes should be nicely cleaned from propolis, and care taken in every way to place the honey in market in a neat and attractive package. The boxes which each case is to hold should be placed upon the scales and weighed before packing. With a little care in selecting boxes, fractions of pounds in a case may be avoided, which is desirable. The net weight should be neatly marked on the case.

EXTRACTED HONEY.—The quantity of liquid honey placed upon the market is increasing each season, and finds ready sale in nearly every style of package, from jelly cups to casks holding 500 lbs. If fruit cans are used, let them be of some standard make, and pack them in crates of twelve each, as shown in figure 2. Each can should have an attractive label, indicating the quality of the honey. For the past few seasons we have shipped largely in tin cans, holding 10, 15, and 20 lbs. At present the demand is for casks, or firkins, holding from 150 to 200 lbs. Such casks should be well made, and bound with wooden hoops, which should be nailed in place, and the casks well coated with bees-wax, inside, before filling. To do this, they should be allowed to stand in the sun until they are quite warm. The wax should be applied quite hot. Pour a quart into a cask, and cork up tight, then roll and turn it, until every spot is touched, when the melted wax may be poured out. The warmer the cask, the hotter the wax, and the quicker the work, the less wax will be required. Avoid filling the casks too full with cold honey, for if allowed to stand in a warm place, the honey will expand, and cause the casks to leak.

Fig. 2.—HONEY IN CANS.

PREPARATIONS FOR WINTER.—All openings at the top of the hive should be closed so as to keep the interior

warm, which will tend to continue breeding later in the season, and thus aid in securing a larger number of young bees for winter. Combs of honey from the heaviest hives may be changed for light ones in less prosperous colonies, and each thus have a sufficient quantity of food for winter. Each hive should contain about 25 lbs. of honey. Avoid exposing honey, whereby robbing may be induced. Where few hives are kept, the different operations may be performed morning and evening, when the bees are flying less freely, and robbing will be less likely to occur.

HONEY YIELD.—From the hive mentioned in August Notes, honey has been taken as follows: July 12, 45 lbs.; July 20, 106 $\frac{1}{4}$ lbs.; July 26, 50 $\frac{1}{2}$ lbs.

NO PATENT.—I am receiving letters frequently which complain that unscrupulous parties in various sections of the country are endeavoring to collect a fee for the right to use the New Quinby Hive. One individual in Seneca County, N. Y., claims to have secured a patent upon it, after it has been before the public ten years. I wish to state that all such claims are fraudulent, as all of Mr. Quinby's inventions were given to the public *free*.

Harvest Home Picnics.

The successful gathering of the harvest signalizes the most joyous season of the farmer's year. It is the fruition of his hopes, and the reward for his labors. In many other countries the occasion is celebrated in various appropriate and interesting ways. "Thanksgiving Day" in America partakes of this character, and is especially endeared to the New England heart, but we need something nearer harvest time—a festival which can be held out of doors, while the fields and woods still are fresh and green. In short, country people need a Harvest Home Picnic, not necessarily at the drawing home of the last load of ripened grain from the fields, or of fruit from the vineyard or orchard, but sometime in August or September, to celebrate the gathering of the harvest, and express our thankfulness for the gracious gifts we have received. And when with pleasure-taking is combined some other good object, the occasion may be one of visibly lasting benefit. Such an affair was a church picnic and festival the writer had the pleasure of attending about the middle of August. The little country church had a small debt, which its honest people wanted to pay. So some bright woman suggested, and it was decided to combine a picnic, a fair, and a harvest home festival, in one. A gentleman loaned his splendid farm, and had a fine grove cleared up and the many natural attractions of the place put in order for his visitors, employing all his spare hands in the work for some days. The creek was dammed for boating, and a "Cruise Island" and rustic bridges made. Evergreen arches adorned bridges and paths; a beautiful natural bower was formed by clearing out the rubbish about a giant but fallen willow, and seats were constructed here and there through the grove. Simply painted signs on plain boards indicated the various localities. One neat banner of white cloth gave the programme; another had the words "Harvest Home Picnic;" a third, "Faith, Hope, and Charity—the greatest of these is Charity." Then the company came—villagers, farmers, and city visitors. Tents were pitched over tables, from which sandwiches, cake, coffee, ice-cream, and confectionery were sold. The gypsy tent was unique; on the ground were displayed various trinkets of woman's handiwork for sale, and not the least attractive were the gipsies in quaint and pretty costume; outside was a veritable gypsy cart, and a pot hanging from a crane over a smouldering fire. Flower girls spread their tempting wares in the shade, near the "Bower." "Rebecca at the Well" was dressed attractively; the well—a big milk can partially sunk in the ground, and surrounded by rocks and ferns—dispensed lemonade to the thirsty crowd at "only five cents a glass." Games—such as an apple race, a sack race, a foot race, and a tub race—and the ascension of fire balloons made fun for the people, and brought prizes of ice-cream and lunch for the winners. A mock art gallery and a lace maker were among the novelties. One of the marked attractions was horse-back riding by a young lady of the farm, with her instructor. They each drove a "tandem," and made their well trained horses pass through pretty evolutions and perform various feats. These exercises called to mind the good old times when ladies generally rode so much and so well, and brought the wish that the many country girls who have the opportunity would engage more in this graceful, as well as healthful, pastime.—The net receipts were considerable, helped along by a small admission (10 cents) to the grounds; and best of all, the day was delightful, everybody had a good time, none felt bored, and when sundown came, many felt sorry that the day was done. Some enjoyed a social party in the evening (which helped swell the proceeds), and had a pleasant drive home by moonlight. Altogether it was a day and a programme that might be copied—at least in its outlines—to the pleasure and profit of many a country town.

Railways of the World.

INTERESTING FIGURES.—According to statistics recently published at the beginning of 1877, there were 184,002 miles of railway in the world, distributed as follows:

United States.....	74,095 miles.	Egypt.....	975 miles.
Canada.....	4,200 miles.	Rest of Africa...	544 miles.
Argentina Repu'e.....	990 miles.	Total in Africa...	1,519 miles.
Peru.....	970 miles.	In Australia.....	1,921 miles.
Brazil.....	836 miles.	Sundry.....	20 miles.
Rest of America, 2,329 miles.			
Total in America, 83,429 miles.		Total in World ..	184,002 miles.
Germany.....	17,181 miles.		
Great Britain.....	14,791 miles.		
France.....	13,492 miles.		
Russia.....	11,555 miles.		
Austria.....	11,852 miles.		
Italy.....	4,815 miles.		
Turkey.....	960 miles.		
Rest of Europe.....	13,781 miles.		
Total in Europe, 89,490 miles.			
India.....	6,527 miles.		
Rest of Asia.....	1,162 miles.		
Total in Asia.....	7,689 miles.		

[Estimating for the increase since the above tables were made up, the present length of constructed railroads is believed to be 205,000 miles; and adding for double tracks, switches, stations, etc., the total length of track is estimated at over 256,000 miles.]

The total cost is given at \$16,313,500,000, of which \$10,386,000,000 is allotted to the 89,490 miles in Europe, (\$116,135 per mile); and \$5,927,500,000 for the 94,592 miles in the rest of the world. In last month's *American Agriculturist* we gave the cost of the railroads in the United States as \$4,568,597,249. (\$61,659 per mile), which leaves \$1,358,902,752 for the cost of the 11,152 miles outside of Europe and the United States, (or about \$122,000 per mile). The average cost of all the World's Railroads is about \$83,700 per mile. The total value of the Real and Personal Property of the United States, for 1870, was \$30,068,518,507, or less than twice the cost of the railroads of the world. It will be seen that $\frac{7}{10}$, or two-fifths of the railways of the world are in the United States. It is only 53 years since the first railroad was opened to traffic (the Stockton and Darlington in England, Sept. 27, 1825; and only 23 years ago (in 1850) there were only 18,600 miles of railroad any where. There were, therefore, 165,492 out of the 184,002 miles built during 26 years, or 6,323 miles a year, or over 20 miles for each working day. Reckoning an average of 25 pounds of iron to the foot of iron rail, the 256,000 miles of track requires 67,584 million pounds of iron (67,584,000,000 lbs.); or to help the conception, say 1,535 pounds for every man, woman, and child, in the United States (reckoning them at 44 millions.) Yet this amount would make little impression upon the vast stores of iron provided in the bowels of the earth, or in a small coating of its surface. (The specific gravity of iron is about 8, making the weight of a solid foot 500 lbs. The 67,584,000,000 lbs. of railroad iron would make 135,168,000 solid feet of iron, or a mass about 514 feet every way). What will be the figures, when the rest of North America, South America, Asia, Africa, Australia, and the larger ocean islands are supplied with the railroads that can be profitably built and used. As all railways have ties about 7 feet long, and averaging, say one to every 24 feet, some of our arithmetical readers may find amusement in estimating the amount of timber required, the amount of ground to grow it, the necessary amount to be constantly growing, if the ties require a renewal once in seven years, on the average, with no new railroads.

A Farm Order with the Right "Ring."

A New York gentleman, carrying on extensive business, owns a large farm, to which he goes with his family during the summer. There are many workmen employed, who are under the immediate care and direction of the Head Farmer, or Superintendent. Our friend finds among his files, the following order issued by the Superintendent, on March 23d, last. It has the right ring—is firm, but conciliatory and stimulating—of a kind that a general would issue to men going into battle; and were not these men going into a real battle? With such a leader, and imbued with the spirit of the order, they will conquer themselves and their bad habits, and the results will show a balance on the right side when the season's work is summed up. We solicited a copy of the "Order," and here it is:

"Now, we are going to start on full time, and perhaps for the season; that will depend upon circumstances. In the first place, I want every man to take good care of tools, and keep them in their places when not in use. Next, be on hand promptly to commence work. Next, he always sure that it is time to quit, before leaving your work. Never stand listening to somebody telling yaras in working hours. Despise tattlers; let us have peace, and with that industry. Never be found watching the

overseer, but let your work show that you have been busy in the absence of your overseer. Let us try to have it said of the men 'Only see the amount of work done for the number of men.' Also, so conduct yourselves, that I can say to the proprietor, 'We have a choice lot of men.' This I can do with a good will, if you do so conduct yourselves; if not, I cannot, and you will lose your jobs. So all this, you see, is for your own interests, and if you will not study your own interests, I cannot be expected to."

Repairing Water Pipes.

When water pipes are burst by the frost, it is easy to repair them in the following manner. The break is usually as seen at *a*, and is caused by the expansion of the water in the pipe when freezing. In repairing such a break in a lead pipe, first bring the edges near together by hammering, then scrape the surface around the broken part, and solder it; or the piece may be cut out, and a new piece inserted. But for iron pipes, and for lead pipes, when it is not convenient to solder them, a different plan may be followed. A strip of stout canvass soaked in a melted cement, made of pitch and brick dust, is wrapped around the pipe, as shown at *b*, until the injured part is covered, or a piece of sheet rubber may be used as at *c*, taking care that the edges do not meet over the break. If the broken edges of the pipe are sharp and likely to cut the covering, file them down. After the wrapping is placed, it is "served" over with copper wire or tarred hemp as illustrated at *d*. A "serving" mallet is used for this purpose; it is made of a piece of wood hollowed to fit the pipe, and with a hole bored through from the center of the hollowed part to the top of the handle. The wire or hemp is passed through the hole, and as the mallet is made

MENDING BURSTED PIPES.

to rotate around the pipe it lays the cord or wire in an even coil upon it. The wrapping may be laid tightly by pressing upon it as it enters the handle of the mallet, or by twisting it once around the same as it comes from the ball. When it is firmly bound, the end may be fastened in any secure manner, and the whole covered with a coating of the pitch and brick dust. These directions will apply to all sorts of pipes where the pressure is not very great; otherwise the wrapping will need to be made stronger to resist the greater pressure.

Report on Insects Injurious to the Cotton Plant.—The Commissioner of Agriculture has appointed Prof. J. H. Comstock, of Cornell University, and Prof. A. R. Grote, of Buffalo, N. Y., special agents to carry on observations and experiments in connection with insects injurious to the cotton plant. These gentlemen, together with several other local observers, who have been appointed in different parts of the cotton belt, will act under the direction of Prof. Riley, the Entomologist of the Department, who has prepared a circular letter of inquiry to be sent to correspondents throughout the South. From this we learn that it is the intention of the Department to make an exhaustive report on the insects injurious to the great staple, and do for the South what the United States Entomological Commission has already done for the West. Such a report, strange to say, has never yet been made, and under Prof. Riley's charge, we have every confidence that it will prove, like his other similar work, full, thorough, and reliable.

A Home-made Wind-mill.

"W. B. W., Mendon, Ill., sends a description of a home-made wind-mill. The manner of making it is as follows: Procure some 2-inch oak boards; saw out a disk (*a*, fig. 1,) about 16 or 18 inches in diameter; make a square hole in the center 2 x 2 inches; bolt the arms to this as shown. These must be of good, hard wood, about 3½ feet long by 2 x 2 inches thick, for an 8-foot wheel. Chamfer off one side, and screw on the cross pieces, *b*, *b*; upper one 14 inches long, lower one 9 inches long. These must be put on at an angle, so as to set the wings diagonally to the wind. To these nail thin pine weather-boards, allowing the ends to extend a

Fig. 1.—WIND-MILL AND PUMP.

little beyond the outer cross piece. After the wings are all bolted on to the center piece, bore a small hole through the end of each arm, and pass a stout wire through and around the entire wheel, taking a hitch around a nail driven in the end of each arm. For the standard or tower, saw out two wheels or disks of wood, making a hole four inches in diameter in each. Place these four feet apart, and nail stout slats all around, making a drum open at both ends, (this is shown at *c*, in fig. 1); four inches from the top of this, at *d*, place a collar, nailing it on securely. Now take a board five feet long, 1½ foot wide, and two inches thick (fig. 2); make a hole in this to fit over the end of the drum on the collar; put another collar on top of this; fasten it securely, and we have the turn-table. To one end of this board put on boxing for the wind-mill shaft (see fig. 2). The shaft for the mill should be of hard wood, shaved or trimmed round, with smooth bearings left for it to work in; but squared at the end, and fastened in the hole in the center of the wheel. To one end of the shaft attach a crank so as to give a 4-inch stroke (*e*, fig. 2); to this attach the pump-rod, which passes down through the drum, as shown by the dotted lines. For the vane, take a 2 x 4-inch scantling seven feet long; mortise the cross pieces as shown in fig. 1; make a frame, and cover with stout canvass or sheet iron. To stop the mill in case of a storm, turn the vane around at a right angle to the wheel, as shown by dotted lines in fig. 2. This greatly lessens the wind-resisting power. The whole apparatus may be held up on a tower by nailing the ends of supports to the drum; or by making a small,

Fig. 2.—SHAFT, CRANK, TURN-TABLE, AND VANE.

square-topped tower, and letting the drum down through a hole. Make a swivel in the connecting rod to the pump, to prevent twisting of the pitman.

What About the "Cow Milkers."

It is very desirable to have some appliance for lessening the disagreeable work of hand-milking. We have been looking and hoping for such an implement more than a score of years as Editors, and more than twice that time as owners of cows. With a drove of cows to milk before and after school hours, when on the paternal farm, we tried to devise something that would draw the milk, especially from kicking and sore-teated animals. Straws, quills, and wooden tubes, with carefully smoothed ends were used, but discarded after one of them drew blood, and a fractious cow ran away with another and pushed it entirely into a teat. A friendly eye and ear have always been turned to those hringing to this office anything that gave the least promise of success. Probably not less than twenty devices have been examined, and we have travelled many a mile to look into and test various contrivances. Some have appeared feasible at first, but continued practical testings have always brought some unfavorable results.

We mention this experience to let it be known that the first party who will bring out a good practical cow milker will have the earnest good will of this Journal, and all the help it can give him. Such an implement, indeed, is one of the great wants of the day.* If seeking new business, we would give more for the patent of a successful, trustworthy implement that would milk the millions of cows than for a machine for any other purpose we this moment think of. From our earliest recollections of farm work, onward, only one more tiresome, disagreeable work comes to mind, viz., raking hearded barley from before an old-fashioned threshing-machine; that capped the climax! We say thus much to stimulate inventors to continue their efforts.

What of the Milkers now in Use?

During two or three years past, sundry tubes have been brought out—hard rubber, ivory, bone, silver, silver-plated; tubes to be used singly, and those united by flexible rubber pipes. They have been tried by three of our Editorial Staff, and by other trustworthy gentlemen. As these have been made so carefully as to seem to be incapable of doing direct injury, and as those of our Staff who have tried them have found them useful with sore teats, have discovered no direct injury in their own experience, and have not been able to say there is a decreased flow of milk from their continued use, we have allowed them to be advertised in the *American Agriculturist*—not with great confidence in their having much value, but partly because of the good faith of the advertisers, partly because they seemed incapable of injury in careful hands, and especially because, being inexpensive, we have hoped a wide trial of them might result in their favor. But we are not prepared to unqualifiedly recommend anything we have yet seen. Some recent reports have come of direct injury, shown by blood, when used by unskillful persons, proving that they can not be entrusted to the ordinary run of milkmen, or milk-maids. Careful, skillful owners are warranted, we think, in having one set on hand for temporary use for badly sore, or cracked teats, and we hope they will secure and personally experiment with them.

An important question is yet to be settled. The natural process is, suction by the calf, accompanied by the pushing, "bunting" motion. Milking by hand partly supplies this natural action. But, will cows generally continue to secrete and yield a full supply of milk, if it is drawn away quietly through milking tubes, supposing it to be always done with care.

*The U. S. Census for 1870 reported 8,935,392 milch cows; the American Cyclopaedia gives for 1874 a total of 10,906,800. There are doubtless at least 12,000,000 milch cows now, (probably nearer 15 millions). To milk 12 million, twice a day, with an allowance of only five minutes for each milking, requires a daily expenditure of time equivalent to 2,000,000 hours, or 200,000 persons to be constantly milking 10 hours a day. Allowing every person who milks at all to have, on the average, 3 cows, not less than four million persons go through the operation of milking twice every day, good cows, and bad, and indifferent. If good milking, by hand even, could be secured continuously, the product would be increased at least five per cent—an enormous sum in the aggregate—to say nothing of unpleasant work, spoiled tempers, and spoiled cows.

Some assert that they will. That is the question now. We are anxious to believe that it will be so, but frankly confess we are yet much in the dark. To settle this question, it will be necessary to have a long continued, thorough trial, upon a considerable number of cows, of known milk yield capabilities—part milked with and part without the instruments, and with such care in feeding, and other items, as to leave no questionable elements to vitiate the results. The trials, to be of value, must be made under the careful supervision of persons of good judgment, and entirely disinterested in any milking-machine, or patent. The Patentees of one or more of these milking-machines, if they have confidence in them, and we are sure some of them appear to be confident, ought to be able to secure such thorough tests. We think the subject of sufficient importance to warrant its being taken up by some State Agricultural Society, or trustworthy Dairy Association. Though not involving a chemical question, would it not be a legitimate work for the Conu. Agr. Experiment Station, for example?—having the trial say on Mr. Webb's farm, under the supervision of Prof. Johnson and his assistants? Other Institutions at the West and South might make similar experiments.

Very Gratifying Figures.

Any farmer, or any business man, who produces and sells more than he buys, is by so much improving his financial condition, provided he keeps up the productive capacity of his farm or business, and does not diminish his stock on hand. The same is true of a Nation. That the productive ability of the United States is increasing, despite some "wearing out of the soil," is evident. Millions of new acres are annually brought into cultivation; and there is also a yearly large increase of live stock, implements, machinery, etc. The statistics of our foreign trade have just been completed for the year ending July 1st, 1878, for the entire country, and they stand thus:

July 1st, 1877, to June 30th, 1878.	
Exports of Produce and Manufactures.....	\$694,884,200
Exports of Gold and Silver.....	33,739,215
Total Exports.....	\$728,623,415
Imports of Merchandise, etc.....	\$437,051,533
Imports of Specie.....	29,821,913
Total Imports.....	\$466,873,446
Excess of Exports over Imports.....	\$261,749,979

That is, during a single year past we have sent \$261,749,979 more to other countries, than we have received from them, and are so much richer, even though the money went to pay up our indebtedness abroad. During the previous year (ending July 1st, 1877), the excess of exports was \$166,539,917, or a total excess for two years of \$428,289,896. During five years, ending July 1st, 1878, the total exports of products, including gold and silver, amounted to \$3,242,634,153, and the total imports, gold and silver included, were \$2,585,415,658; excess in our favor, \$657,218,495, or an annual average of \$131,443,699. This total excess of exports over imports for five years nearly equals one-third of our entire National Debt. An annual excess of exports equal to that of the past year, would in eight years about equal the whole of the National Debt, allowing only for the principal.

Science Applied to Farming.—XLV.

The Ville Formulas and System of Manuring.

Of the numerous formulas for fertilizers for special crops, no others have attracted more attention than those of Prof. George Ville of Paris, whose investigations at the Experimental Farm at Vincennes during the past 25 years or more, have been discussed, and whose writings are read the world over. These formulas form a part of a system of manuring explained in Ville's books, several of which have been translated into English. An early one which covers part of the ground, and includes most of the bad and many of the good points of Ville's doctrines, has been lately republished in the form of a pamphlet, with the title "High Farming without Manures—Six Lectures on Agriculture." Another, later and more complete, is called "Chemical Manures." A third gives a

brief exposition of the system, in the form of a dialogue, and has, I think, been translated under the name of "The School of Chemical Manures."

Ville's fundamental proposition is: "The profit from farming depends upon the quantity of fertilizers given to the land.....Without fertilizers the yield is small, the profit nothing, and the final result loss. With abundant manuring, the yield is increased, and the profit certain, for the excess of expense is but the half or the third of the price of the excess of the harvest crop."

The great problem for the farmer then is to get manure. The cattle he wants and can profitably keep for other purposes will not generally supply enough. More stock will be a burden, and the manure costly. Ville proposes chemical manures instead. In what he calls "The System of Agriculture which ought to Prevail," instead of cattle kept as a necessity for making manure for grain and other crops, he recommends to "buy manure, and raise such crops and keep as much or as little stock as will be most profitable."

The Essential Ingredients of Manures.—"Complete Manures."

According to Ville, of the dozen or more constituents of dung, four—nitrogen, phosphate of lime (phosphoric acid), potash, and lime, which constitute about one-tenth of its weight—are "the regulators *par excellence* of production, and the only ones with which agricultural industry need occupy itself." His formulas for "complete manures" supply these four ingredients, the nitrogen as nitrate of potash (saltpeter), nitrate of soda, or sulphate of ammonia; the phosphoric acid in the form of superphosphate; the potash, in either nitrate of potash, or other potash salts, and the lime as sulphate of lime (land plaster). He says, that "the mixture of these substances has the same properties as dung." The "complete chemical manure is to the barn-yard manure, what the metal is to the ore." "It is farm-yard manure divested of all useless matter."

The formulas which are made for different crops, based not upon the composition of the plant, but upon its assumed capacity for getting its food from air and soil, and the effect of the different materials upon its growth. "Each of the four regulating ingredients has its own functions which are of more or less relative importance, according to the nature of the plant to which it is applied...." No one can do any good without the coöperation of the other three (though if either is supplied in abundance by the soil, it need not be included in the manure.) Give the others, and each has its own predominant action for a certain list of crops.

"Dominant Ingredients."

Ville gives "the name *dominant* to the ingredient which, for a given crop, plays a more important part than the others." Thus:

"Nitrogen is the predominant ingredient for the cereals as Wheat, Barley, Rye, Oats, and for Colza, Sugar beet, Hemp, etc."

"Potash has an especial influence upon Peas, Beans, Clover, Lucern, Flax, Potatoes, etc."

"Phosphoric acid is especially beneficial for Turnips, Ruta-bagas, Radishes, Indian Corn, Sugar-Cane, etc."

"Lime seems to exert no especial preponderating action upon any plant, but is necessary for all."

The practical inference is that in preparing a fertilizer for a given plant, we must reduce the subordinate ingredients as much as we can, and put in a good deal of the dominant. To sustain his propositions, Ville cites a great many experiments; some made by himself in pots or in the fields of the Experimental farm at Vincennes, and others by farmers in France and elsewhere. In an experiment on wheat, for instance, one plot received a "complete manure;" from another the lime (sulphate of lime) was omitted, while the third had no potash, etc.

Fertilizer.	Yield of Wheat per Acre.
Nothing	15.88 bushels.
"Complete Manure,"	56.44 "
"Complete Manure," without "lime"	53.33 "
"Complete Manure," without Potash.	40.44 "
"Complete Manure," without Phos. Acid.	34.66 "
"Complete Manure," without Nitrogen.	18.18 "

The wheat suffered more from lack of nitrogen than from lack of any other ingredient. Again, with sugar-beets, starting with a complete fertilizer which supplied 360 lbs. of superphosphate, 180

lbs. of nitrate of potash, 270 lbs. nitrate of soda, and 360 lbs. of sulphate of lime, per acre, when more lime, potash, or phosphoric acid was added, the yield was not affected, but when the nitrogen was increased, the yield rose with it. From such experiments as these, Ville infers that nitrogen is the dominant ingredient for wheat and the sugar-beet, and consequently he puts a large proportion of it in his formulas for these crops. He insists, furthermore, that the form of combination is important, and uses sulphate of ammonia for wheat, nitrate of soda for sugar-beets, and so on. For clover, beans, peas, etc., he recommends little or no nitrogen, because these plants are found to get very little if any good from nitrogenous manures. He explains this by assuming that such plants get all their nitrogen from the air, and do not need it in fertilizers. Of the theory once held by many, that plants assimilate the free nitrogen of the air, Ville is now almost the only prominent defender. He claims that clover gathers all its nitrogen from the air; that harley and rye get 80%, wheat, 50%, and sugar-beet, 60%, from the air, and the rest from the soil. This assumption, I think, has very little of experimental proof to rest upon. Much more investigation is needed to settle the question.

Concerning the mineral ingredients, phosphoric acid, potash, and lime, Ville's rule is to restore all that the crops remove, and a little more to make up for what is leached away by the water in the soil below and beyond the reach of the roots of plants. In this, he very strangely ignores the resupply which every soil keeps up from the decomposition of the materials it contains.

Ville proposes "complete manures" for all crops, but at the same time recommends farmers to test their soils by experiments, in order to find whether these already contain and can supply any of the ingredients, and if so, omit them from the fertilizer. He lays a great deal of stress upon these experiments, and gives very full directions for making them. Where chemical fertilizers are to be used as auxiliaries to farm manure, he recommends to use the dominant ingredient for the crop; thus, for wheat he would add sulphate of ammonia or nitrate of soda; for corn, or turnips, superphosphate, etc. Ville claims that

Chemical Fertilizers are Superior to Farm Manure

for several reasons: (1) They bring larger crops. In proof of this he cites several hundred experiments made by agricultural schools, societies, and private individuals, on wheat, oats, rye, barley, maize, potatoes, sugar-beets, sugar-cane, etc., in France, Belgium, Germany, Italy, and other countries. In 51 experiments with wheat, in which chemical and farm manures were compared, the chemicals brought larger crops in 47, less in 3, and the same in one case. In 92 experiments with sugar-beets the artificial fertilizers brought the best results in 67 cases, the dung in 20 cases, and both the same in 5 cases. In 32 experiments with potatoes, the chemical manures brought more than horse-manure in 25, less in 6, and the same in 1.—(2.) The chemical fertilizers are cheaper. To substantiate this, he makes extended comparisons between the cost in France of farm manure and the corresponding chemical materials, and calculates that the manure is the dearer by some six per cent.—(3.) Chemicals are always at command, and in just such kinds and quantities as are needed, the only limit being the amount of capital to be in-

vested.—(4.) The ingredients of chemical manures are ready for use at once, while in yard-manure they are slowly available.—(5.) Chemical manures are more easily and cheaply transported, handled, and applied.—(6.) Chemical manures can be divided so as to use for each crop its predominant regulating ingredient, and in each case only what is needed. Thus, in a rotation, nitrogen can be used for wheat or oats, phosphates for corn or turnips, and potash for clover. Or, if the soil supplies enough of any one ingredient for any crop, it can be omitted from the fertilizer and its cost saved.

Continuous Use of Chemical Manures.

To the question whether chemical manures alone can be depended on and used with profit year after year, Ville replies, "Yes, under two conditions: 1st. Give the land in fertilizers more phosphate of lime, more lime, and more potash than the crop takes from it.—2d. Give it about 50% of the nitrogen of the harvest." W. O. ATWATER,

Wesleyan University, Middletown, Conn.

A Flemish Milk Wagon.

A correspondent now travelling in Europe, sends a photograph of the milk cart common in the streets of Antwerp, Belgium, which we reproduce in the engraving presented above. For a dog to draw a cart is a curious thing for many readers, as also is the peddling of the milk from door to door by a woman, but is an ordinary sight in that country. The cans are of the ordinary sort, from which the milk is drawn by means of the dippers, the long handles of which are seen sticking above the sides of the cart.

Oleomargarine.

What it is—What it is Used for—Its Effects.

Though much has been published in the *American Agriculturist* on Oleomargarine, we give the following summary for the benefit of the large class of readers who show by their letters that they are not already familiar with the subject. Oleomargarine is made from the caul-fat of beef animals, by a process and machinery, which separates the fat from the tissues. So far it is clean, and, of itself, as clear suct, is unobjectionable; but some claim that dirty grease, and even refuse hog-fat are also used in the process. Manufacturers claim that it is identical with butter, because both are fat, and come from the same animal, and are similar in composition. A comparison will show the fallacy of this assertion. Oleomargarine consists exclusively of the three fatty compounds—stearin, olein, and margarine. All animal fats, of which butter and suet are chief representatives, are

made up mainly of these three substances, though in varying proportions, and often with additions. Butter is composed of stearin, olein, margarine, butin, myristin, caprin, caproin, caprylin, and butyrin—six extra ingredients which are not contained in oleomargarine; and these extra six constitute something like ten per cent of the butter, and the aromatic flavor and other peculiar characteristics of the butter are mainly due to their presence.

It is claimed that the absence of some of the components of butter make the oleomargarine superior in keeping quality to butter. Be this as it may, it does not make butter of oleomargarine.

Butter is a product peculiar to the udder of the cow, and is obtained by separating from the milk, by churning, the fats which compose it. Oleomargarine is formed in other tissues of the animal, is composed of different ingredients, and is separated by heat and processes which produce a different result. Though chalk and marble have nearly the same constituents, yet chalk is not marble, nor is marble chalk; even so oleomargarine is not

butter. Oleomargarine is then essentially tallow, or other fat prepared by churning it with a little real butter to form a product which has been often sold for butter—now, fortunately, prohibited by law in some States. Oleomargarine quite closely resembles butter in appearance; but it has a peculiar, strong taste—unmistakable after it is once tried—and leaves a sticky disagreeable sensation in the mouth, similar to that caused by greasy soup; this bad flavor can be tasted for hours after eating it. For cooking purposes it may serve as a substitute for poor butter, and may even be used upon the table by those who are not particular in such matters. It makes a pastry, which, though good enough while hot, is very tough when cold. A

very large amount is sold in the markets of the country, for use in cooking and for table use in cheap restaurants, and by the poorer classes. The usual price for this "butter" is 15 cts. per pound. Much is also used in cheese factories to take the place of the cream used for butter-making. The product is sold as whole milk cheese, when not prevented by law or the honesty of dealers; and large quantities are shipped abroad as American cheese.

The effects of such a product in the market are great and manifold, as often pointed out in the *American Agriculturist*: Its low price seriously affects all the lower grades of butter and cheese; it imposes on the public a sham for a reality; it endangers our foreign markets for good dairy products; and all of these will in turn have other and deleterious effects, which any one can trace. The remedy is simple: let every State, that has not done so, by law compel its sale under its own name, and let dairymen combat it in the market, by not making either butter or cheese which can be compared to it, but produce only superior articles, and get the better price they are sure to bring.

Bees, Bee Keepers, and Honey.—The annual convention of the National Bee-Keepers' Association will meet in the Cooper Union, N. Y. City, on the 8th of October, at 12 noon, and a show of bees and their products will be held at the American Institute Fair on and after September 20th.... As to shipping honey, a prominent dealer informs us that the supply of honey now in market, and on its way thither, is so great as to practically overstock the market, which fact should induce farmers to hold their stock for a while.

A Norfolk Polled Heifer.

We recently gave a picture of a Norfolk polled cow. Herewith is presented a portrait from one published in the "Agricultural Gazette," (Eng.) of a heifer of this breed: it is Rosebud 2d; dam, Rosebud 1st; sire, Rudham Hero; bred by Mr. Savory of Rudham Grange, England. The breed is attracting considerable notice in that country, and a Herd-book has been established for the protection both of breeders and purchasers, as well as for the preservation of the purity of the breed, which is worthy of introduction and cultivation in America. The dairy interest is growing to an enormous extent, and in its development over greatly differing localities, there is not one really good kind of dairy stock that may not find a place, in which, for certain purposes, or to suit certain tastes, or necessities, it may surpass all others in form and usefulness. That the Norfolk polled cattle desire the high reputation they possess, is proven by the fact that at the commencement of the herd-book, more than seven hundred carefully bred animals were offered for entry. There is but one full herd of them in America—that imported and bred by Mr. Taber, of Patterson, N. Y.—with a few scattered animals in different sections. From the numerous enquiries made concerning them, since our previous illustration, it seems that they are exciting considerable interest. This would be augmented if a few energetic importers of other cattle would turn their attention to these. That such ventures would be profitable, seems to be quite certain, considering the prices realized for Jerseys at every importer's sale. It is not alone as dairy cattle, that this breed deserves notice: the illustration shows that these animals will produce beef as well as milk. The deep brisket, the full fore-quarter, the rounded barrel carrying a full loin, and the general symmetry would not disgrace a short-horn of the first families. To produce good milch cows and excellent beef is sufficient to give character to any breed; but when in addition it has the advantages of being easily kept on moderate pastures and feeding, and being without the dangerous and useless horns, it becomes still more valuable and desirable. With the present outlook

rights, representing 10,000 acres of land, were sold in 1877, and the present year 290 rights were disposed of up to July. As progress is made and experience gained, or better methods are practised, the water is used with more economy, and the breadth of land that can be watered is consequently enlarged. So far, streams only have been utilized,

Cross-Bred Jersey-Ayrshire Cows for the Dairy.

Which is the best cow for farm and for family use? Where the farmer uses his cows for butter making, experience would go to show that the grade Jersey

CROSS-BRED JERSEY-AYRSHIRE.

but it is now proposed to make use of the water of occasional floods by confining it in reservoirs. In this way the supply may be largely increased, and hundreds of farms made in places that are now barren, not only because they are deficient in water for three-fourths of the year, but because they are torn and devastated by freshets, and inundations at other seasons, when the water would be useless for vegetation. It will doubtless be but a short time

is essentially the farmer's cow, a fact widely appreciated. The mark of the Jersey is now noticed on every hand in the beautiful and picturesque colors and graceful forms of the cows seen grazing in the meadows, and dotting the pastures. No other cow is so easily kept, or more docile, or gives a richer return in butter for the food consumed, than the grade Jersey. But something depends upon the cow from which the grade is raised. Unless the dam of the cow is a copious milker, and is able to transmit this quality to her progeny, the principal end sought in the crossing is missed. The Ayrshire is the most prolific milk cow. For large yields, and for easy keeping, she is unsurpassed. To cross an Ayrshire cow, with a well selected Jersey bull, ought to give the best dairy cow that can be readily produced. The large milk yield of the Ayrshire, is united with the large cream yield of the Jersey, and we have all we can procure in one way from the Jersey, multiplied by the excess of the yield of the Ayrshire. Herewith we give a portrait, the first ever published, we believe, of a cross-bred Jersey-Ayrshire cow. This is a young animal, a few days over two years old, but has been milking for five months, and has produced over one pound of butter per day from a little more than eight quarts of milk. She was bred by Mr. Thomas Fitch, of New London, Connecticut, a gentleman who has been experimenting in crossing the Jersey upon every known breed of cow, including the "Sacred cow of India," for over 30 years, and who long ago settled upon the Jersey-Ayrshire as the best cross possible for large yield and rich quality of milk. The cow in question is a white and brindle in color, with a golden yellow skin which shows through the fine short silky hair at every place where white prevails. As a proof of the easy keeping of this class of cows, the original of the illustration has been kept in excellent condition from the mowings of less than half an acre of lawn with two quarts of middlings daily; and upon this feed has been, and is, producing a little more than one pound of butter per day. For so young a cow this performance is worthy of being recorded among those of the many good cows whose portraits have from time to time been exhibited in the *American Agriculturist*. It is evident that this is one of the best cows for the farm and for family use.

NORFOLK POLLED HEIFER.

for an extensive trade in beef and beef cattle, their characteristics will carry much weight in the choice of live stock for both milk and general farming.

Agriculture by Irrigation.—The cultivation of land by means of irrigation is gradually extending in Colorado, California, and other localities. In the colony of Greeley, Colorado. 250 water

before agriculture will call for the services of engineers, to make available the practically unlimited opportunities for impounding water in the mountain valleys, and using it for irrigation. We hear already of such intentions in the valley of the Arkansas, which possesses a supply of water sufficient to convert its present dry fields into gardens for several hundred miles along its course.

Among the Farmers.—No. 32.

BY ONE OF THEM.

When the strawberries were in blossom, and rye not yet in the ear, and when men were getting out the manure for corn, and the shouts of the plowmen were heard all over the land, on a drizzly rainy day, with lucid intervals, and just chill enough to make us feel that grass was the only thing especially benefited, and with the good company of an old friend, Mr. Wells, of Wethersfield, the writer visited

"The Ranch" of James B. Olcott.

This is Wonderland to the readers of the *Connecticut Courant*—a land of mysterious production and of a peculiar charm, not well defined, but real. Mr. Olcott's readers have learned all about the sand barren, and the yellow pines, and scrub-oak woods, and strawberry plantation. They know "Old Ring-bone" and the "Twenty-dollar horse," and the Alderney steers, by reputation at least, and so did I. Now, to understand both the man and his home, needs a long acquaintance, and the affection engendered of it, but I may be allowed to say to the readers of the *American Agriculturist*, that Mr. Olcott is a reformed Californian. That is, he has had the desire to wander and see the world, and the rough and savage, as well as the smooth and placid waters and ways of life, and then, ten years ago, settled down upon his native sands. He believes that a man as is a man, can get a living, and a home, and home comforts—and that includes fruit from June to June—as well as everything else that a regenerate wanderer is naturally heir to—home, joy, peace, meat and vegetables, especially if his heart is full of the milk of human kindness, and his stables of Jersey cows—provided he goes to work the right way, on almost any kind of soil.

Well, we caught him at home, or he caught us, and no Tartar either way. He had big boots of rubber or well-grained leather, which furnished us for a tramp through the wet grass; and we inspected the strawberries, the grass land, the big patch of sand-barren he was reclaiming with 40 or 50 loads of beautiful leaf and stable-manure compost to the acre, the low woods which were annually robbed for the leaves, and many other interesting things. We inspected the house of his own planning and building, with the dairy and stables adjacent, which are quite too close for any but people who love neatness and hate ill odors; and we partook of a frugal lunch, served by the gentle house-mother and her daughters, and seasoned by kindly welcome and instructive talk.

Mr. Olcott built his house with much of Donald Mitchell's sentiment, for a combination of the useful and beautiful—that is, making beauty a thing of use, and useful things graceful and fair; and so he carries on his work, a useful sentimentality pervading both his composts and his letters. It is framed into his buildings and recognized in the width of his doorway and the breadth of the grass-plot, in the weedless garden, in the kindly whinny of Ring-bone, and the contagious laugh of the proprietor of the "Ranch."

One thing surprised us, there was less of what one may call sandy-land farming—that is, plowing in of green manure crops, agonizing after organic matter in the soil (which is always disappearing), and the use of crops known to flourish in light soils, like cow-peas, for instance. Manure from the barnyard, which was really one great compost-heap, is Mr. Olcott's dependence for crops of all sorts. The supply of this is augmented in every possible way, but chiefly by leaves from the woods. This robbing of the woods checks their growth in a great measure. Yet we may surely take our choice, when we have it, between promoting the growth of timber, and increasing the yield of corn and fruits.

Treatment of Ailing Animals.

If there is any one thing which gives a real distress to a humane man, it is sickness and pain in a dumb brute which he can not alleviate. If his children are sick, he or his wife, or the good grandmother, has knowledge and nostrums which are administered with some confidence—"simples"

which are useless and harmless, or possibly beneficial. If these fail, they usually have near at hand

"The Village Doctor,"
Whose ancient sulky, down the village lanes,
Dragged like a war-car, captive, ills and pains."

If, however, the animals are sick, we have no one to turn to—cow-leeches and horse-doctors, blacksmiths and stable-boys, whose tender mercies are cruelties, are always ready to physic and purge, to sear and torture, with "every thing and device they can think of,"—nauseous mixtures, the very enumeration of whose ingredients would be hardly fitting matter for these pages, if no important good were to be gained by it. So the poor things suffer, and get well in spite of us, or they die in agony while we stand by helpless. This state of things is all wrong, and might and must be remedied.

Veterinary Surgeons.

The number of educated veterinarians in this country is very small; they all find employment in or about our large towns, and as a rule are a very respectable class of practitioners. To them, however, whenever we can, we confide the treatment of our live stock; but not one farmer in 10,000 can do so. We have two or three veterinary schools which are struggling with poverty or lack of appreciation, and would do well if they each graduated a score of practitioners a year. Medical schools for training human physicians abound, and their graduating classes number hundreds. Every hamlet, almost, at the East, and every village in the Middle and Southern States, has its educated physician; while throughout the Western States they are numerous, and within reach everywhere in civilized regions. Nine-tenths of them are making no more than a fair living, and many are failing to do that. Other professions and callings tempt them from their own that they may get better pay. Not that they do not love their profession, nor that they are not qualified to practice it, but it will not support them.

Why Should Not Physicians Treat Animals as well as Men?

If a physician has all he can do to treat ailing humanity, certainly the animals must be neglected; but when, as at present, the "doctors" are making a poor living, or none at all, what should prevent them from treating the animals? Nothing hinders but a false pride. Study and experience will enable any physician to do it with success. Comparative anatomy is studied in all our medical schools; comparative pathology should be. The knowledge of animal diseases is of great service to a physician. In fact, man and animals are found to have so many diseases in common, that animal pathology is quite essential to reasoning upon, and treating many of the ills that man is heir to. Were it to become a general custom among physicians to treat animals, and to charge for it, we might confidently anticipate the

Most Gratifying Results.

These, or some of them, I venture to enumerate. First, the physicians would make a better living; besides, they would at once become more important to their constituencies. Second, the country would have a corps of efficient observers, on the watch for infectious or contagious diseases among animals, and quick to detect and report upon unusual animal diseases of any kind, whenever they might break out, thus providing an efficient safeguard against their spread, and against filling our city markets with diseased meat, or the killing of such for country consumption. Third, the wealth of the country would be increased at once by the saving of the lives of many animals, and ultimately by the better understanding and prevention of various murrains and maladies. Fourth, improvement in the sanitary surroundings of both animals and men, and a much higher degree of health and soundness.

Effect of "Fertilizers" in Moist Seasons.

The present season has been an exceptionally favorable one for testing fertilizers. At least I have found that, so far as I can judge, they have produced up to the time of writing, very nearly a maximum effect. There is a danger, unless comparative trials are made with different fertilizers, of overestimating the excellence of those we do try.

I have one standard kind applied liberally to corn and to mangels, and its effects are so extraordinary that, had I not other rows of corn and roots which look now equally well, though manured with other articles—I should not say equally well, perhaps—and yet one patch looks as if it would produce just as much as the other. I observed one curious result. In planting corn, 20 rows were manured with superphosphate in the hill; 20 upon the hill after planting; 20 rows upon the hill and hoed in after the corn was up, and 20 more after the corn was three to four inches high. The only notable result was that the second 20 rows had to be replanted; not one quarter of the hills did more than sprout, and then the plantlets' kernels softened, a very few making a struggling life. After replanting, the corn did well, and now makes a good stand. I get about half the result from superphosphate harrowed in broadcast with corn, for fodder, as when applied to corn in drills—that is, when the fertilizer was scattered in the furrow, and corn sown in and covered. I am confident that although that in drills was put in a week later, there is now fully twice the burden of fodder upon the land that there is upon the broadcast piece.

Usefulness of "Sludge Acid."

The readers of the *American Agriculturist* probably know of the hue and cry that has been made in New York about the use by the fertilizer makers of what is called sludge acid—that is, the sulphuric acid which has been employed in extracting the impurities from petroleum, and which by the process becomes highly charged with oily matters, and emits a nauseous odor. The superphosphate of lime made with this retains to a considerable extent its peculiar, pungent, "aromatic," and very disagreeable odor. Now, insects are sensitive to odors, and I find that wire-worms avoid potatoes where this fertilizer is used, and that my corn has not been troubled with cut-worms and white grubs where this was on or near the surface. I attribute the freedom to the presence of the sludge acid used in the manufacture of the superphosphate, and am confident that it does no harm to the plants.

What Kind of Wheat.

Important to Grain Farmers.

For the benefit of our readers who are wheat-growers, we would like each one who has tried any one or more known varieties to write us *what* kind has done the best with him. If each will answer in order the following questions, the compared replies will doubtless be of value to each and all of them:

- (1.) What variety of Winter Wheat has succeeded best with you?
- (2.) What variety of Spring Wheat has succeeded best with you?
- (3.) What is your soil?
- (4.) What manure and other fertilizer do you use?
- (5.) What manure or fertilizer has given the most satisfactory results with you, and how much have you used per acre where such results were obtained?
- (6.) How much seed do you use per acre?
- (7.) What is the yield of crop you obtain?
- (8.) Does the Hessian Fly or Wheat Midge trouble your crop?
- (9.) When do you sow winter wheat?
- (10.) When do you sow spring wheat?
- (11.) What price do you obtain per bushel?

Be sure to give your post-office, County, and State. Answers are desired from farmers on rich virgin soils, where no manure is used, as well as from the old sections. Please answer each question separately, and in the order as above put down, and write the number against the answer given to it.

Grazing Pastures.—When a pasture is insufficiently grazed, considerable of its product is wasted. The tufts of uneaten herbage which often cover a large portion of the surface, are not only left useless, but injure the next year's grass. To keep a pasture in good condition, the droppings should be evenly scattered once a week, and the

fouled spots be sprinkled with plaster. In addition, it will pay to follow cattle with a few sheep, which will clear off the spots left by the cows. The finest pastures are those kept the most evenly grazed; and to secure this, grazing lands should receive constant attention from the first to the last of the season. But close cropping, by animals which are not all the time in the pasture, will, after a while, exhaust it; to provide against which, 150 to 300 lbs. per acre of fine bone or superphosphate, should be applied yearly in the fall or early spring. The phosphates are first exhausted from pastures; an average cow requiring about 100 lbs. of phosphoric acid in her milk yearly, and growing animals a large amount for their bones.

Talks on Farm Crops.—No. 19.

By the Author of "Walks and Talks on the Farm,"
"Harris on the Pig," etc.

We had a trial of a new binder. After the people had gone, the Deacon remarked: "Well, it did the work better than I expected. It did not tie the bundles quite tight enough to suit me, but I suppose that can be easily regulated."

"One thing is certain," said I, "binding by machinery is an accomplished fact. There are several machines that do the work well. Which will prove to be the best remains to be seen. This one ties the bunches with string instead of wire, for which many will prefer it. Before I buy a machine, however, I will wait to see if some one can not invent a binder that will bind corn-fodder as well as wheat, barley, oats, timothy, millet, etc. We have cut corn-fodder for several years with a reaper. It does the work better than it can be done by hand. It cuts the corn, and throws it off into bundles ready to be bound, and if the machine would also bind it, I would raise 20 acres. I would drill it in rows 2½ or three feet apart, cultivate it thoroughly, and cut it during hot weather—early in September; put the bundles into stooks, as we do wheat, and let them stay until well cured."

"Is not that," remarked the Deacon, "easier said than done?"

"No. I have managed corn-fodder precisely in that way, and do not wish for better feed for milch cows, sheep, or horses. But I have also had considerable trouble in curing and handling it. I have had part of a field where the crop proved every way excellent, and part where it was almost worthless; and that is not all, the poor fodder entailed twice the labor of the good. Why this difference? Simply because one was cut in the last of August, and the other two or three weeks later. The one was thoroughly cured during hot weather; the other grew larger, and was more difficult to cut, and the weather being cooler, with more or less rain, it was not fully and quickly cured, and lost much of its color and sweetness."

"I have not tried it, but I feel pretty confident that a crop of corn-fodder, if sown early, of an early, small variety of corn, and cut early, can be cured in August or early in September, so that it can be put in the barn or stack. The Germans call it 'Maize hay,' and I believe it can be so well cured that it will keep as well as clover or timothy. Why not? I have corn-fodder that is to-day (July 24th) as thick and heavy as it can stand on the land. It is in drills, 35 inches apart, and it is almost impossible to walk through the rows. Now, if such corn-fodder is cut the first week in August, and tied up into sheaves as we do wheat, and put in rather open stooks for a week or ten days during one of our 'heated terms,' there would be very little more sap in it than there is in clover hay. Stow it away in a stack holding, say ten tons, and do the work during a bright, hot day; and if you are afraid it will not keep, put a layer of dry straw between each layer of bundles of fodder, and finish off the top of the stack with straw."

"Or," said the Deacon, "put it in the barn at once, and have done with it."

"That," said I, "would sometimes save labor, but all of us have not barn room to spare at that season; and if the field is some distance from the

barn, it is quicker to stack in the field, and draw in the fodder when we are not so busy as now."

"Busy as now," exclaimed the Deacon. "I hope not! We have not had such a busy harvest for years. Everything ripened up at once. Wheat was ready to cut before we were half through haying. Then the bugs were on the potatoes, and the weeds in the corn, and an extra man could not be had for love or money."

"It is your own fault, Deacon," said I; "there are men enough if you would only take the right course to get them. I have heard you remark again and again, 'If a man comes here we have got to support him. He has got to have a living, and he will get it out of us.' And yet every year you go through precisely the same experience as you have this year. It is nothing new. It is so every harvest, only you forget from year to year. Next spring you will forget again. If a man wants work, you will say, 'I guess I can get along without you,' and you send the poor fellow into the city. He would be glad to work for 75 cents a day, and board himself. But you depend on hiring an occasional day hand. You leave undone much work that could be profitably done, and when the pinch comes you look around for your day men and they are not to be found. The Squire wants them, I want them, and others want them. One man told me that there were eight farmers after him one morning last week before breakfast. You offer \$1.50, \$2.00, or \$2.50 per day, and board, for men and boys not actually worth 75 cents a day. And you will do precisely the same thing next year."

"Well," said the Deacon, "I have made up my mind to hire an extra man next spring."

"I am glad to hear it; but that is not just what I want to see done. I want you and the Squire to encourage more good, steady, sober, industrious married men to settle in the neighborhood. The value of farm property, other things being equal, depends on the population. Our profits come from labor and not from land. We want more men."

"That is so just now," said the Deacon, "but it is not so in winter and spring."

"As a matter of fact," said I, "we had more men at work on this farm last December and January than we had during harvest, and still more in March, April, and May. There is no necessity for this fluctuation in the demand for labor on our farms. Unsteady employment and high wages are utterly demoralizing. But one thing is sure, we shall not lower wages by refusing steady work to steady men, and thus compelling them to turn tramps, and then paying high wages to some miserable scallawag for two or three weeks in the busy season. The system is all wrong. It makes young men idle, impertinent, unskilful, and vicious. There is work enough for all, and there are men enough to do the work. But the less we do, the less there is to do. If we plant less corn, there is less to cultivate and husk; and the same for other crops and in other industries."

I know that this is not talking about "Farm Crops." And yet the subject lies at the foundation of our agriculture—if not at the foundation of our national prosperity. I will not say that the cities need less labor, but I am sure the country needs more. How are we going to get it?

Do not be afraid to sell a good steady man an acre or two of land, and let him put up a small house. Or, if you prefer it, put up the house yourself and rent it to a good man, and give him work. And give his boys work. Geo. Geddes once told me, "The only way you will get a foreman is to raise him." And the best way to get good farmmen is to let them grow up on the farm. I have two boys that were born on this farm, and that have worked for me ever since they were able to work at all. They know my ways—know the land and the stock, and the implements and machines, and every year they become more useful and valuable. They are happy and contented, and will in time have farms of their own; and better still, know how to manage them and take care of good stock.

A young man is far better off on a farm than in a city. Farming is no longer the dull, plodding, uneventful, dreary existence that we read about. There is sufficient hurry, pressure, and excitement

to stir the blood and stimulate the efforts of an energetic boy or man. Our seasons are so short that a farmer must work lively. Whatever his hands find to do, he must do with his might. He must battle with the winds and storms, with rain and snow, with heat and cold. He must fight if he would win. He must be a plucky man. He must work with a will. If there is no snap in him he had better find some dull, steady, slow, unvarying employment in the city. He is not the man for modern agriculture. Our work is constantly changing. It is rare that we have three days of steady labor. We have in the spring to plow for barley, then harrow, then drill in the seed. Then sow clover seed. Then roll. If it rains, we go into the cellar and get potatoes ready for planting. When the stubble land is too wet to work, we plow on the sod. We have oats to sow, and corn, potatoes, and beans to plant. We are beginning to use more or less artificial manures. We are raising more mangel-wurzel and other root crops. We are constantly getting improved implements and machines, and needing more intelligence and skill in our operations. We have not time to get tired of putting in the crops, and of hoeing and cultivating before the grass is ready to cut; and a bright boy can relax his muscles by riding on a new mowing machine. Then comes the harvest. But what is haying and harvest compared to what it was when I was a boy? If we got through in six weeks we did well; now, with mowers and reapers, and rakes and unloading forks, we can do double the work in half the time. If a shower stops us we "green" the potatoes. Then there is the excitement of thrashing with a steamer. And all this time the weeds are calling to us, "be quick," "be quick,"—"we are after you," "we are after you." And if we are not lively they will catch us, and then we get a sound thrashing, which, if we are men, will make us work livelier another year. There is no time or chance for dullness on a properly managed farm.

"But what has all this to do with the labor question?" More than any of us realize. We want better men. And to get them, we must commence with the boys. We must get more married men into the neighborhood, and give their boys a good agricultural education on the farm. We must teach them. If you have a boy loading hay and two men are pitching, do not take delight in throwing the hay just where the boy does not want it. Put a good forkful on the corner, and another to bind it. The pitcher, if he is a man, can do half the work for the boy. Then in unloading, instead of the two big men standing on the top of the bay looking at the boy pitching the hay up to them, let one of them help him to unload occasionally. I have known two men and a boy drawing in hay; the boy was unloading. I had a spare man, and sent him to the stack to help. Where do you suppose he went? Did he help the boy? No. He got on to the stack and looked down at the boy, pulling and working at the load of hay below! And that is as much sense and manliness as you will find in half the old-fashioned common farm hands. Then when the load was off, if the men wanted a drink of water, the boy must go and get it for them. We must raise a better class of men. Look at the boys. They will soon be men. It will pay to educate them. Do not give them the poorest tools. If you have a new plow let the boy take it. Do not ask him to do the hardest work, or if you do, relieve him as soon as possible. These two boys I speak of will do anything I ask them. When thrashing with a machine, if there were two men and one of these boys on the straw stack, if anything should happen requiring two hands, and I called the boy and one of the men down, the chances are that the other man would think he could not take away the straw. He would give up the ship; but I could safely take the two men away and leave the boy. I could depend on him to strain every nerve and muscle to keep the thing going. He would know that I would relieve him the first moment there was a chance. I have had him in just such a situation more than once, and when I have gone to his assistance, he did not relax his efforts, but the expression of his face said plainly, "I knew you would come." He held the fort, and will do it again whenever I ask him.

Hints and Helps for Farmers.

TEMPORARY WHIFFLE-TREE.—One of the very annoying conditions in which a man occasionally finds himself is when he breaks a whiffle-tree away from home. A subscriber sends a plan of relief from the fix as follows: Procure a piece of the best timber to be found of the proper length; hew it down, and notch it so as to fit the clevises as shown at *a*, fig. 1. The clevises are attached as shown at *b*, and the happy man can go on his way rejoicing, if only he has an axe with him. This he will al-

Fig. 1.—CHEAP WHIFFLE-TREE.

ways have if he follows the hints given in the *American Agriculturist*, that no one should go from home with a team or carriage without one, and also take a coil of copper wire, and a spare bolt or two.

A BARN CLOSET.—A very useful closet may be made in the corner of a barn or stable by nailing to the wall a common packing box, which can be procured at any country dry goods store for a few cents. The cover is fastened with hinges, and serves as a door for the closet. Two shelves may be fitted in the box. A place is thus provided for storing away the small odds and ends lying about a barn or stable, where they may be kept clean, and can be found in a moment when wanted. The closet, as it will appear when fastened up, and resting upon a cleat at the back, is shown at figure 5.

A WATER PAN FOR CHICKS.—To prevent young chicks from fouling the water in the saucers in which it is given to them, take a common fruit can, remove the top, and cut notches in it as shown in the engraving (fig. 4). The chicks can reach the water, but they can not foul it by running through.

A RAKE FOR A STABLE.—"A. W. L." sends a hint in the form of a sketch of a rake and scraper combined, which he uses to clean out his stables. The rake-head is a strong piece of hard wood, beveled on one edge, and furnished with teeth upon

Fig. 2.—RAKE AND SCRAPER.

the other. It is fitted to a proper handle, and will serve to rake out half-used litter or manure, to scrape the floor, or to push the manure into heaps for convenient removal. It is illustrated in fig. 2.

HOME-MADE SAW-BUCK.—"A Reader" gives us a sketch of a very serviceable "buck" for sawing wood, made of four pieces of round wood. These are hewed into the form shown at fig. 3; a two-inch hole is bored through one of each pair of legs to receive the trimmed top of the other leg, and the legs are joined in the usual manner by a two-inch cross stick tightly wedged at each end. To prevent the legs from coming apart, the holes for the cross stick may be bored so as to

Fig. 3.—SAW-BUCK.

slightly notch the leg, which is then held firmly by the cross stick, and can not work loose readily.

MANURE DUMPING.—Yokes wear out and break sometimes, and the writer has recently seen a capital use for them when broken. The piece was attached by a chain and staple to the axle of an ox-cart, and was used as a rest or runner whereon to place the tail of the cart in dumping. Only a part, say a quarter of the load, is wanted in one heap, so

the cart is tipped up, a portion drawn out over the tail-board, then it slides along on its yoke-runner to where the next heap is wanted, and so on. The runner, when not in use, will take care of itself, or may be hung up under the cart-body. The illustration, fig. 6, represents one seen on the Welles brothers farm, Wethersfield, Conn.

Value of Sheep as Manure Makers.

Pasture alone is not sufficient to maintain sheep in profitable thrift, especially in the approaching breeding season; in addition, a daily ration of grain is needed. When the pasture is poor the quantity of grain should be liberal. With good pasture, a pint of mixed corn and oats, or rye and buckwheat, is little enough; with poor pasture half as much again would be required to keep full-grown sheep or growing lambs in proper condition. In some sections cotton-seed meal is coming into great favor for feeding sheep on poor pastures, a half pint being fed to each one daily. It is a nutritious food, and makes an exceptionally rich manure; and the quality of the dung of animals as a manure always depends on the quality of their food, for the dung is only the food, changed by the processes of digestion, less the portion taken into the system as nutriment. There is a mistaken idea, which has been fostered by writers who know little about

Fig. 6.—TO DUMP A MANURE CART.

sheep, that these animals have the unusual capability of living upon weeds, briars, brush, and coarse herbage, and not only of getting fat thereon but of greatly adding to the fertility of the poor soil. A sheep, however, has no power to make something out of nothing. By reason of its fine mastication, and its vigorous digestion, it can, perhaps, exhaust its food of more of its nutriment than any other animal except a fowl; and its manure, by reason of this finely comminuted condition, rapidly decomposes, and is at once effective as a fertilizer. To make our flocks thrifty—to secure strong lambs, heavy fleeces, and good mutton—we need to feed the sheep, and we must do this if we would turn the flock into vehicles for spreading manure and enriching the soil. It is a fact, that sheep supplied with a regularly given ration of one pint of grain per day, besides pasture, made in 60

Fig. 5.—CLOSET MADE FROM A BOX.

days, 20 lbs. each more weight than a flock on as good pasture without grain; and the value of the extra flesh more than paid for the grain. In addition, the

fleece made more growth, a large proportion of the ewes conceived twins, and the lambs came stronger and were better supplied with milk. And, as a matter of course, the droppings of these sheep must have been richer in fertilizing value than those of poorly-fed sheep. The good shepherd careth for his sheep, and he has his reward in the richest return that can be made by any of our farm animals, for the food and care given. Instances of the successful use of sheep as fertilizers of the soil are given so frequently, but without any reference to the methods of their use, that it has become a general belief that nothing else is needed to make a poor farm rich. But if any novice is led to try it for himself, both he and his flock will come to grief.

Fig. 4.—POULTRY WATER-ING DISH.

How to File and Set a Hand-Saw.

When a saw is in bad order, the teeth are irregular in length, and pitch, as in figure 1. This occurs through improper filing, and results in the saw working hard. The reason is that a saw irregularly filed, or set, cuts only with the longest teeth and those that have the most set. To remedy these defects, it should be pointed and filed until the teeth are all of even length, and are pitched so that the front of each tooth is at right angles with the back of the saw, as seen at fig. 2. The saw is fastened into a clamp (see fig. 6 on opposite page), which consists of a pair of jaws fixed upon a stand, and moved by screws as shown. An end view is given at fig. 3. The ends of the teeth are brought to a level by running a flat file lengthwise of the blade. The best form to give the edge is a slight curve from end to end of the saw, making the middle slightly rounding *outwards*, never hollow. The handle of the saw when in the clamp

Fig. 1.—A SAW IN BAD CONDITION.

should be to the left, and not be changed during the filing. The part held in the clamp should be filed completely before being moved, if the jaws are not long enough to hold the whole. On a rip-

Fig. 2.—SAW PROPERLY FILED AND SET.

saw, the teeth will be filed square, as shown at *a*, fig. 4; on a cross-cut, they are beveled upon alternate sides, as also shown in fig. 4. Both sides should be filed without moving the saw, which may be done by changing the position and manner of holding the file. A beginner should provide a handle at least a foot long for his file; this will enable him to hold it steadily, which is very necessary for good work. The proper size for a file is 3½ inches long for a saw having eight teeth to the inch. A saw is set before it is filed. The set given for easy cutting should be such as to make the cut as wide as twice the thickness of the blade. Several good sets are sold at the tool shops which are self-regulating, and make even work. The set of a cross-cut saw will make it appear as at fig. 5 when looking lengthwise at the teeth; and an even channel should be seen in which a knitting needle could be

Fig. 3.

Fig. 4.

Fig. 5.

laid and moved from end to end. If only a few of the teeth are short, they need not be pointed, but may be

touched with a few strokes at each filing, until the rest are worn down to them. If one has no clamp, a strip of hard wood may be laid upon each side of

Fig. 6.—SAW CLAMP.

the saw, and the whole held tightly in a vice. In filing, the strokes should be made *from* the operator, and not towards him. The file should be grasped firmly in the right hand, while the tip is held lightly between the finger and thumb of the other. A safe rule is to work slowly, and to test the teeth as the work progresses with a try square. As long as the faces are kept at right angles with the blade of the saw, the backs must come out right. "W. D.," of Beaver Co., Pa., sends some of these suggestions.

Raw-hide Horse Shoes.

A method of shoeing horses with raw-hide, has long been in use on the plains, and found so serviceable and convenient that it might doubtless be found useful in many places where there are long periods of hot weather. There are also cases frequently occurring, in which disease of the feet might at least be alleviated by the temporary use of shoes cut from raw-hide or properly prepared sole leather. With these, that portion of the foot which needs the most precaution, viz., the crust or walls of the hoof where it meets the sole, will be preserved from contact with hard or rough surfaces;

LEATHER SHOE.

while the frog, generally too much protected, will reach the ground and become subjected to healthful action. For farm work, upon smooth soils free from stones or gravel, this kind of shoe will be useful during the summer season. A simple strip of raw-hide or sole leather, well filled with hot pine tar to make it hard and waterproof, will be sufficient for general use. A more durable shoe may be made of two or more thicknesses, fastened together by copper rivets as shown in the illustration.

Cattle Sheds.

Shelter should always be provided for cattle or other live-stock, both from the summer heat and

Fig. 1.—CHEAP CATTLE SHED.

the winter's cold. It is not necessary that the sheds should be costly, many a farmer who knows their need may wait too long for them unless they can be cheaply constructed and of cheap materials. It is now time to think about sheds for use in the coming winter, else when winter comes they will not be ready. The material may be such as will suit the purse of the owner, and the style the same of whatever they may be made. At figure 1 is a plan of a shed which can be built for about 50 cents a running foot, or \$50 per 100 feet, which will accommodate 25 to 30 head of cattle. The extra quality of the manure made in a shed of this

character in one season would repay its whole cost. This is built against the side or end of a barn, or a high board fence. A scantling, *a*, is spiked to the wall at a convenient height. Poles, *b*, are set in the ground 2½ feet from the wall, and sloping backward, as shown. Scantlings or battened poles are spiked to the pieces, *a*, the tops of the poles, *b*, and to posts, *c*, to support the roof. The front can be enclosed wholly or in part with boards nailed horizontally. The feed trough, *d*, is raised from the ground, and can be reached through openings in the barn wall. If abundant litter is thrown in this shed, the cattle may be kept in it for a whole winter, in perfect cleanliness; and the manure being trodden hard, will remain moist and inoffensive. In a similar shed, 40 feet long, 14 head of cattle have been wintered and kept dry and comfortable; the manure when removed in the spring was two

Fig. 2.—A CATTLE SHED OF BETTER BUILD.

feet deep, and in the best condition for immediate use. The animals were not fastened, but if it is thought desirable to tie them, each post will make a stanchion for hitching to. Of course it will be

Fig. 3.—EASILY MADE PENS.

understood that such sheds are not recommended for occupancy by milch cows in very cold localities.

A better looking, but not more serviceable building may be made of timber and boards nailed and spiked together, without mortises or tenons, for about four times the cost of the shed above described. A section of the frame is shown at fig. 2. The sills, 6x6 (*a*), are halved together at the ends and pinned or spiked. The joints should be thoroughly painted with pine tar before putting them together. The boards are then nailed to the sills, fastening and bracing the corners until the plates, 2x6, (*b*, *b*), are nailed to the boards. A girt, 2x4, (*c*), is then fastened at such a height as to be made to support a floor if necessary, or about 7 feet. The beams of the floor should be of 2x6. The building may be 10 or 12 feet high if 20 feet wide. The rafters are then fitted to the plates and strengthened with collar pieces of board (*d*). Posts, 4x4, may be put in at the corners, and a few studs of 2x4 be added at every 4 or 6 feet around the walls. A building so constructed will be found quite stiff; and with a shingle roof, and painted with Johns' Asbestos paint, it may be neat and shapely. If room is needed for storing hay or grain, the upper floor may be removed and the building be filled to the peak.

Or pens of rails, poles, slabs from saw-mills, or other rough timber, may be made as shown at figs. 3 and 4. These are built up after the manner of log

Fig. 4.—SIMILAR TO FIGURE 3.

houses, the ends of the poles at the entrances being secured by stakes driven down upon each side

into the ground, and fastened by wires or withes, twisted around them. The pens may be covered with cornstalks, coarse hay, or straw, and a

Fig. 1.—BUTTER STAMP.

quantity of the same used for protection on the exposed sides. As a protection in the field for sheep and pigs when about to produce their young, such pens will be found very useful; and in the West, where corn stalks and straw are a burden, such cheap sheds will be found an economical shelter.

Butter Stamps and Packages.

There is rivalry amongst fancy butter makers to excel, not only in quality, but also to offer their product in the most acceptable form, and in attractive as well as convenient packages. The favorite method of putting up

butter for immediate sale, is that of pound cakes, ornamented with a stamp and marked in the center, so that each can be divided into half pounds for use on the table. For this, moulds and stamps are used. A convenient and shapely butter stamp is shown at fig. 1, bearing the maker's initials. Being square, the prints may be packed upon the shelves in any butter-carrier without loss of space, which is an advantage. A package for round prints, known as the Lancaster Butter-Carrier, is shown at fig. 3. This holds 48 round prints, each contained in a separate cup of tin. In warm weather the central cups may be left out and the space filled with ice. This method preserves the butter in good shape, and enables it to be handled by the retailer in the best manner. A

Fig. 2.—BUTTER PAIL.

useful package for distant shipment, is the white-oak pail, shown at fig. 2. It is made of several sizes, to hold 5, 10, 20, or more pounds. The smaller ones are convenient for the consumer and for the retailer; and the oak being free from objectionable scent or flavor, will preserve the fine qualities of the best butter from deterioration. They can be packed in barrels or boxes when put up for shipment.

Fig. 3.—BUTTER PACKAGE.

the oak being free from objectionable scent or flavor, will preserve the fine qualities of the best butter from deterioration. They can be packed in barrels or boxes when put up for shipment.

Seed Wheats.—Now at planting time, it is important to choose a good variety of seed wheat. With every care in preparing the ground, all may be thrown away and lost by sowing a variety that is either not hardy or not prolific. Of two varieties sown side by side, and grown under the same treatment, on the writer's farm, one was hardly worth thrashing, while the other will yield at least 25 to 30 bushels per acre. The better of the two is the Clawson wheat. Of the fall wheats, we have also grown the Treadwell, Fultz, Lancaster Red, with the Clawson, which have proved hardy, almost

proof against fly and the midge, and they yield well, and make excellent flour. A newly imported variety, the "Challenger," grown this season upon Long Island, has done very well, and from its permanent reputation in England, is worthy a trial here.

Levelling the Bottom of a Drain.

When drains are laid so that the slope is uneven, they soon become useless. This is caused by the retention of water in the hollow portions, and by the deposition of sand or other sediment in these low spots until the tile or water channel is completely closed. In making a drain, the first thing is to cut the ditch. If this is perfectly done, laying the tile is a simple matter that can hardly go wrong. The chief consideration is to get an even slope without any depressions, which is a very difficult matter, and however well the surveyor's levelling and staking may have been, if the workman is incompetent, or not closely watched, there will almost certainly be hollows in the course of the drain. Where a stream of water is running in the ditch, it is not difficult to notice any deviation from a regular slope; but when the ditch is dry, it is far from easy, especially when the slope is only a few inches in a hundred feet. A guide made in the following manner, will serve to indicate any variance from a proper grade. It consists of a few "cross-legs" made of wooden bars, 2 inches wide, 1½ inch thick, and 5 feet long (fig. 1). They are fastened together with bolts, so that the legs can be spread or closed, and may be set astride the ditch. When the ditch has been roughly dug out, the level may be accurately fixed in two or more places, over each of which a pair of legs is set, and over these, a strong thin cord, such as a stout linen fishing line well oiled, is stretched and secured as shown. It is a matter of convenience how many of the legs are used; two will be sufficient in most cases, although a number of them may be used over an extended drain upon regularly sloping land, as a guide for the first excavation. When the line is set up, it may be prevented from sagging, by the use of a few intermediate supports as shown at *a*. These are square rods 1½ inch thick, furnished with sharp iron points, and each having an arm, a foot long, as indicated. The bottom of the ditch may be graded from this line by testing it occasionally with a plumb-bob. By testing every foot, a perfect grade may be secured, and in laying the tile, the test line may be again used for certainty. It is necessary in placing the "cross-legs," to have them set so that the line supported by them is parallel with the proposed grade of the drain. This may be done by spreading the legs apart or by drawing them together.

A correspondent sends a sketch and description of a method of making levels upon the surface, which may also be adapted to the levelling the bottom of a drain. The implement consists of a "pair of legs" with a cross-bar, upon which is mounted a common builder's spirit-level. The legs are made of strips 1 inch thick, 3 inches wide, and 11 feet

Fig. 2.—A LEVEL AND PLUMB.

long. The cross-bar is 9 feet long. The spread of the feet is exactly 16½ feet, or 1 rod. The level may be temporarily used to secure the correct hanging of the plumb-line, and the marking of the notch, shown at figs. 2 and 3, and may then be laid

aside. When the instrument is correctly marked, a block of wood one inch thick may be placed underneath one foot, and a mark made where the plumb-line strikes the cross-bar, as shown at fig. 3. A scale may thus be noted upon the cross-bar, each mark showing a deviation of one inch in a rod, or 1 in 198, and the scale may run each way from the middle. It would be better to read thus, 4, 3, 2, 1, 0, 1, 2, 3, 4, and so on; the center 0 showing a level, and the others, 1, 2, 3, or 4 inches slope in 198 feet. In practice, the instrument is placed in the drain to be tested, and the mark beneath the plumb-line

Fig. 3.—LEVEL IN USE.

noted. Whatever this may be, the same inclination should be kept along the course of the drain, and a test made at every 6 or 8 feet if desired. The instrument may be used for laying out drains in the first instance, by placing it upon the ground with the right leg at the starting point, and moving the left one here or there until a proper slope is found, when a peg may be driven in the ground down to the surface, and the right leg moved on to it, when the left one may be used again to find the proper spot. By traversing the required direction until the termination of the drain is reached, and count-

Fig. 1.—A GUIDE FOR GRADING THE BOTTOM OF DRAIN.

ing the pegs, the whole inclination will be ascertained, when the drain may be run in a direct line, from the first to the last peg, avoiding the meanderings. Another level which will serve to test the inclination, is shown at fig. 4. This is marked similarly to that shown at fig. 2, but is differently

Fig. 4.—A HANDY INCLINATION LEVEL.

constructed. The L is made at right angles, and the amount of divergence is shown by the swinging of the plumb-rod. The bottom may be exactly 100 inches (8 ft. 4 in.), and every inch of slope can be marked upon the scale. The handle serves to slide the level along the bottom of drain.

Sheltering Vehicles and Machines.

Notwithstanding the number of carts, and mowing-machines, and horse-rakes, and other tools that we see standing by the roadside or in the field, the year round, most farmers believe in the economy of housing all these things. They know that iron rusts, and that wood-work swells and shrinks with the changes of the atmosphere. They think it is only a question of time that the new carriage house or shed shall be built, where the scattered tools and vehicles will have a permanent home. This waiting to provide the needed shelter is

the most expensive kind of saving. The elements are all the while at work, depreciating the value of the wood and iron that are exposed to the weather. A scythe and snathe hung in a tree through one season, is old, warped, and rusty. Stored in the tool-room it is little changed in look or value; no repairs are wanted, and it is ready for use as soon as the grass is ready. The new cart that is left by the roadside soon goes to pieces; even if painted, the paint soon wears off; the sun cracks paint and wood, the heat expands the cracks, the rain enters the openings, and decay commences, the joints become loose, the felloes and spokes shrink in the dry weather, and the tire must be set often to keep the vehicle in running order. Farmers often overestimate the expense of a tool or wagon house. If they have timber or building stone upon their farms, very little money need be laid out to put all running gear under cover. A roof and siding to keep out rain is the main thing. Flooring is not needed. The bare earth under all wooden wheels with tires, if dry, will answer instead of plank. Just enough moisture is absorbed from the earth to keep the wheel in good condition. The tire will not need setting so often. A shed set upon a bank wall makes a good shelter, and is within reach of most farmers.

The Best Fertilizer.

How to make a formula for a fertilizer for any particular crop or soil, which shall produce satisfactory results, and at the same time be most economical of material—wasting nothing, and using only so much as the special case requires—is a most difficult question for any one to answer, unless he be the best of agricultural chemists, and is thoroughly familiar from long experience with the land under treatment. Yet, just such information as this is what farmers in various sections are continuously writing to us for. The first part of the problem is comparatively easy—i. e., to make a fertilizer which shall produce great results—but what to leave out is a difficult point to settle. Indeed we may say, that this is a point which never can be settled exactly, so great a difference is there between adjacent farms and fields, and parts of the same field even, or further still in the composition of the same spot of ground at different periods. But wonderful progress has been made in the solution of this problem—which involves so much of success or failure in agriculture—within the past few years, and for the most part has been recorded in the *American Agriculturist*. Here is a letter from "J. W. L.," of Lancaster County, Pa:

"Will you please give me what you consider the best formula for making a phosphate for wheat, also tobacco and corn, to be used on limestone soil. Farmers in this County have generally been making their own, and are using more every year with good effect. It is made according to the following formula, viz., for one ton take

600 lbs. Bone.	50 lbs. Salt.
200 " Oil of Vitriol.	300 " Plaster.
150 " Sulphate of Soda.	7 bush. Sand or Ashes."
10 " Nitrate of Soda.	

In this case the same fertilizer is used for three crops of quite different requirements, yet apparently with like "good effects" on each. Tobacco is a great potash feeder, containing about 27 lbs. in 100 of ash; while corn contains 30 lbs., and wheat 34 lbs.; yet this fertilizer contains only what potash is in the 7 bushels of ashes—not over 20 lbs. But the Lancaster County average tobacco crop of 1,500 lbs. per acre requires 80 lbs.; and as only 400 lbs. of the fertilizer are applied per acre, it only gets 4 lbs., and not always that, since the ashes are considered of so little importance as to sometimes be replaced by sand. Yes, the sand is even named first. The same is true of wheat and corn as respects potash, though to a less extent. If this fertilizer produces satisfactory harvests year after year for each of these crops, it is quite evident that the soil where it gives such results, does not need potash, for the present at least. Yet almost any farm in New England, or elsewhere, on which the same sandy-loam soil prevails, would show a very different result, as potash thereon is one of the essentials. And we are inclined to doubt whether the same showing

would be made for many years in Lancaster County. As to the composition of the fertilizer, we see nothing essential except the bone and the oil of vitriol (sulphuric acid). Since the mineral portion of bone is composed almost entirely of lime compounds, when it and the acid are put together, chemical action takes place, which forms a large amount of sulphate of lime (plaster). Why, then, add more plaster? The plaster thus formed in the fertilizer would have a similar effect to the sulphate of soda, and could well take its place; and there is so little of the nitrate of soda as to be of no moment whatever, though 100 lbs. would doubtless have a materially beneficial effect. Even the acid (oil of vitriol) could well be dispensed with, provided the bone be reduced by composting with stable-manure for three to six months. Such a compost, kept heating by occasional wetting (best with liquid manure), and protected from loss of the ammonia by a light covering of earth, will fit the bone for use as well as by using the costly acid.

Thus it will be seen that there is great waste in such home-made fertilizers, even though they produce good results. We have pointed out one or two points of error; but we have not considered the nitrogen or phosphoric acid, either as a whole or in relation to the various crops; nor touched upon the amount of the fertilizer required in each case; the first will have further consideration; the second must be determined by individual experience from year to year on the farm.

Profitable Use For Some Waste Lands.

How will this do? All over the mountainous regions of New England, Eastern and Southern New York, Central and Western Pennsylvania and Virginia, Eastern Kentucky and Tennessee, and so on Southward, as well as in some of the far Western States and Territories, there are very many tracts of high land too stony for cultivation, or even for good pasturage. When the first wood is cut off, a second growth comes up, straggling, bushy, often scrubby. In 15 to 20 years a moderate crop of fire-wood is again cut, but there is little valuable timber.—While wandering over the large farm of a friend on the west side of the Hudson River, the other day, we came upon a sort of table-land field on a hill that had been cleared, and an attempt made to plow and cultivate it; but it was too stony, and the proprietor said he should give it up as not

Fig. 1.—SECTION OF HAY CARRIAGE TRACK.

worthy of attention. All around it were groves of cedar, chestnut, and other kinds. The chestnut trees appeared thrifty. We set to reasoning thus:

A man with pick and spade could dig up and prepare at least 20 places a day that would each furnish a good bed for a young chestnut tree. Putting these in regular squares, say about 12 feet apart, would give 300 trees to the acre. At \$1 a day, this would cost \$15 per acre; on many fields it would be done for much less. An abundance of young chestnut trees that will bear transplanting can be readily produced at trifling cost by planting the seed in a good plot of ground. Allow \$5 for the 300 young trees, and we have them well started and growing on an acre, at a cost of \$20.—One or two days annually, with a long-handled hatchet, or wide chisel, or bush-hook, would suffice to clip out starting under-brush, and trim off side branches from the trees to keep them growing upward, so as to furnish tall trunks for timber. No other expense would be required. The trees set in the small prepared plots will send out their roots among the stones, and grow vigorously, if the ground be not wet or springy. The annual fall of leaves will mulch and enrich the soil. In about 14 years there would be 300 fine trees, each worth at

least 50 cts., or \$150 per acre, for posts and rails, besides not a little fire-wood. The original outlay of \$20 would be doubled by loss of interest. Allow \$10 more for pruning, care, etc., and would there not be a profit of \$100 per acre? Nothing is allowed for the value of the fruit or nuts that would be gathered. We said above that our thoughts run out in this channel, but we are not sure of the

Fig. 2.—HAY CARRIAGE.

feasibility of the plan, and we invite criticisms, pro and con, and any suggestions. Would, or would not the above be better than to invest the \$20 in bonds or mortgages? The land is practically worthless now; if it yields any pasturage, it would yield quite as much with the under-brush kept down, after the trees are too large to be injured by the animals roaming among them.

A Home-made Hay Carriage

A correspondent from Somerset Co. Pa., sends the following description of a hay carriage, which can easily be attached to a barn at any time, but more easily when the barn is building. The rail track is shown at fig. 1. It consists of four pieces of 4x4 timber; two uprights, *a*, and two horizontals, *b, b*. These are as long as may be made necessary by the pitch of the roof, and are framed or bolted to each pair of rafters. The space between the uprights, *a*, is 8 inches; that between the ends of the horizontals, *b, b*, is one inch. The rails which rest on the ends of the horizontal supports, *b, b*, run the entire length of the barn, and are 5x3½ inches, thus leaving a space of one inch between them. The rails are firmly secured by bolts, the heads being sunk even with the surface, so as to offer no obstruction to the wheels.

The carriage (fig. 2) is made of strap-iron bent as shown at figure 3. The wheels *a, a*, are of wood or iron, and flat on the tread; are 5 inches wide, and from 6 to 9 inches in diameter. The iron straps are 2 feet long, 2½ inches wide, and ½ inch thick. The hanging pieces, (*b, b*, figs. 2, 3, and 4,) by which the hoisting rope is supported, are 13 inches long. They are bolted to the carriage as indicated; one is provided with a pulley at

Fig. 4.

the end over which the rope passes, and one carries the catch *c*. The construction of these is shown in detail at fig. 4. At fig. 5 is a movable fastening, upon which the catch hooks itself as the carriage is drawn back to its place, either by a light rope, or a rope and weight. The top piece, *d*, (figs. 2 and 5), and the under piece, embrace the rails *e, e*, between them, and hold them firmly when the thumb-screws are tightened. This part of the catch is moved upon the rail as is found necessary for the hoisting of the hay. The carriage can be used to hoist hay, straw, or grain, either into, or out of the barn, or from one end of the barn to the other, or from either mow to the floor in the middle.

Cats, versus Rats and Mice.

We have never seen any estimate of the damage inflicted upon the farmer by rats and mice, that did justice to the subject. The damage is wide-spread, and outside of the realm of statistics, it would be hardly possible for any farmer to estimate, except approximately, his own personal loss every year from these vermin. He is made aware of the ruin wrought, on almost every part of his premises, and every day in the year. They are in the cellar reducing his winter stores of vegetables, or if walled out therefrom, by stone and cement, they find refuge in the barn, invading grain-bins and hay-mows. They make their homes in the field, under stacks, and shocks of grain. If there is anything tender and edible, they lie in wait for it. How they prize young ducks and chickens, every poultry-woman knows. What a charm there is in seed-corn, and indeed, in seeds of all kinds, for them, every one who saves seeds knows. Cement is good, if faithfully applied, but not one farmer in a hundred uses it; and those who do, find it impossible to keep cement between rats and their grain crops at all seasons of the year. They prey upon corn on the stalk and in the shock, and upon wheat in the stack. They frequent mangers, and pigs' troughs, and the hen-house. Traps are very good, and rats may be thinned out by these ingenious contrivances. But

Fig. 5.

your neighbor does not use traps, and he is always raising rats and mice to stock your premises. The creatures will emigrate without any respect to the graves of the victims you are all the while burying out of sight. A clean house and barn to-day, may be haunted with lively vermin to-morrow. Poison is effectual and carries the war right into the enemies' country. But then it takes a good deal of time to prepare it, and to seclude it from everything but rats and mice. It is not to be forgotten too, that they have a malicious way of crawling into their burroughs, wall in and ceiling, and reminding you of their presence in an ungenerous way. If the evil that men or rats do, would only die with them, we should have some consolation. But it will not. There are so many failures and infelicities about the proposed remedies, that we have come to think better of the old and time honored method of destroying rats and mice. The cat has her drawbacks, it must be admitted. She is noisy, and will sometimes fight the dog, or prevent birds from nesting about the house. But then, she does war upon rats and mice, and makes a business of destroying them. It is literally vituals and drink to catch these vermin, and she educates her offspring in the same habits. Other parents sometimes fail of transmitting goodness. But by birth and education, the cat is a rat-catcher. Every one of her brood walks in the way she should go. She is cheap. Her time is not worth much. She slays, and saves money while you sleep. Let us cultivate cats.

CONNECTICUT.

The Didders as Weeds.—(*Oscuta*).

Those little parasitic plants, the Didders, are well known to those who notice the common things about them. In almost every swampy place their yellowish threads may be seen in late summer, hanging in tangled masses over other plants, upon the juices of which they live. In Europe, one Dodder injures the clover, and another the flax crop. In December, 1874, we figured a Chilean species that threatened serious damage to the Alfalfa fields of California; and in November, 1868, another, that had made its appearance in a nursery, and attacked the young apple trees. Recently, we had another instance of the appearance of a Dodder as a weed. A gentleman in New Jersey, who is experimenting with the choicer basket willows, brought rods from his plantation, 5 or 6 ft. high, which were festooned to the top with the thread-like stems of the parasite. As flowers had not yet appeared, we

could not determine whether it was one of the half dozen or more native species of *Cuscuta*, or a European one, imported with the willows. At all events it is in such abundance as to threaten to seriously injure the value of the willows, and if not exterminated, their culture in that locality will be impossible. The course to be pursued will depend upon the future development of the weed. If that flowers and perfects its seeds so late that the willows may be cut without injury to the stools, then it may be well to wait a while, but if there is danger of stocking the soil with seed before it will answer to cut, then hand-picking of the clusters must be resorted to. As Daddlers always start from a seed that germinates in the ground, and draw their nourishment from the soil until the stems have thoroughly attached themselves to the bark, it will not be difficult, now that the nature of the pest is known, to keep it down in the future.

A Large and Complete Barn.

The plans and perspective view presented herewith, represent the fine stable on Houghton Farm, the property of Mr. Lawson Valentine, Mountainville, Orange Co., N. Y. It is located in a central

The farm buildings are numbered, this being No. 1, shown by a conspicuous figure in white over the main door. The interior exposed wood-work is varnished, making a neat and substantial finish. Systematic work is enforced in the care of the animals, and is encouraged by appropriate mottoes about the stable in the basement, such as the following: Over the horses, "I'll do my best for a kind and generous master" and "Take good care of me and I will serve you long and well;" on the feed passages, "Waste not, want not," and "Be regular in feeding and watering;" over the carriage-way, "Be prompt;" and conspicuously before the eyes of the men when harnessing, the well-known saw of Davy Crockett, "Be sure you are right, and then go ahead;" over the farm harnesses, "A stitch in time saves nine;" over the tools, "A place for everything, and everything in

gates for separating the cattle department from the horses. Another barn serves for stabling a portion of the cattle. Figure 3, shows a plan of the main floor; *a*, is the tool room, on the wall of which are

Fig. 3.—PLAN OF MAIN FLOOR.

the words, "Return every tool to this room;" *b*, contains a horse-power for driving a feed-cutter, thrasher, etc.; *c*, is used as a stowage-room for cut feed, etc.; *d*, is the grain room, provided with bins and convenient shoots; *e*, is a room for the trainer, who there sleeps just over the animals he loves and cares for so well; the room also contains closets for the nicer harnesses. An opening in the ventilator, and a wakeful ear, enables the trainer to hear every sound from below. The letters *v, v, v, v*, indicate the ventilators; *s*, shows the large platform scale, on which every load of hay or grain is weighed as it enters the barn. The floor of the basement is made of brick, laid on edge in mortar, underlaid by concrete. Figure 4 represents one of the horse-stalls. The upper portion consists of iron rods extending from the top of the sides to a railing two feet above, and from the manger to the railing, as illustrated. The stall is 9x4½ ft.; and the manger is 1 ft. 9 in. from front to back. An iron feed trough for grain occupies one end of the manger, indicated by the dotted line at *G*; the remainder is taken up by the hay-box, *H*, the bottom of which is shown by the dotted line; a door in front allows for cleaning out the feed box, and a closet for storage. The box-stalls are also provided with the iron rods for a top-finish, so that a person can easily see into them without entering. This barn has so many conveniences that we have not space in one article to describe them. In its general completeness,—fine proportions, conveniences, and compact arrangement, it has few equals.

Fig. 1.—BARN AT HOUGHTON FARM, MOUNTAINVILLE, N. Y.

position on the farm, about 25 rods from the house, on a side hill, and supplied with water brought from springs. The barn is handsomely proportioned, and with its slated roof and red-painted walls, with black trimmings, presents a fine appearance. For the keeping of the owner's large stud of carriage, saddle, farm, and breeding-horses, it is ad-

its place." There is also the precaution, "Look well to ventilation;" and oft repeated, "No smoking." A clock on the wall marks the moments of wasted or utilized time. Iron-framed lanterns, with reflectors, are made fast to the wall at one end of each passage. Opening into the basement, and extending nearly to the roof are four ventilating flues, each 4 ft. square. Their outer edge is on a line with the drive-way, and the inner side has openings fitted with movable slides, at various heights, which make the flues serve as convenient hay shoots into the floor below. The building is 110 feet long, by 55 feet wide, with 20 feet posts, and is 40 feet from the main floor to the ridge. It rests on a stone basement ten feet high in the clear; this basement

Fig. 2.—PLAN OF BASEMENT.

mirably adapted, and worthy of imitation by any well-to-do farmer desiring a handsome and useful barn; and in its general plan may be followed on a smaller scale by any one having numerous horses and fine cattle to provide stabling and shelter for.

provides comfortable and convenient stabling for the owner's fine stud. The division is shown at figure 2; *a, a*, are the horse stalls; *b*, the harness room, 4 x 25 ft.; *c*, stairs; *d*, box-stalls, 10½ x 14½ ft.; *e, e*, cow-stanchions; *f*, ox-stanchions; *g, g*,

Fruit Growing in California.—Until recently, the California fruit growers enjoyed an enviable immunity from the various insects, blights, and other obstacles with which Eastern growers have to contend. The Californians have shown great enterprise in introducing fruits from all parts of the world, and with them have come the enemy,

Fig. 4.—VIEW OF HORSE STALL.

and for the last year or two, the California Horticultural and Agricultural Journals are almost as much devoted to the extermination of insects and fungi, as are similar papers in the older States.

The Starry Magnolia.—(*Magnolia stellata*.)

Many months ago, Messrs. Robert B. Parsons & Co., sent us the flowers, and later the foliage, of two new Japanese Magnolias, to which had been given the names respectively of Hall's and Thurber's Magnolia, (*M. Halleana*, and *M. Thurberi*), the one in honor of Doct. Hall, a long resident of Japan, and who has been instrumental in introducing a number of Japanese plants, and the other in honor of one of the Editors of the *American Agriculturist*. These Magnolias were first introduced

sion as to quite cover the bush, but are individually smaller than those of the related species, averaging from 3 to 4 inches in diameter. They have an exceedingly pleasing fragrance. The other, offered as *M. Thurberi*, mainly differs from this in the number and size of its petals. For small places, plants of moderate height and abundant bloom, are most desirable, and such really valuable additions as these Magnolias to our collections of early flowering shrubs, are most welcome, and we thank Mr. Robert Parsons for making us acquainted with them.

We have heretofore expressed our regret that botanical names should be given to nursery plants,

A California Succulent.

(*Cotyledon edule*.)

Within a few years, the plants known collectively as "succulents" have been much in fashion. Their compact and low growth, their fleshy leaves, usually arranged in rosettes, and the considerable variety in their color, which is generally of soft and pleasant tints of green, especially adapt them for working out figures in mosaic planting, and allow the production of effects in gardening that are possible with no other class of plants. Under the

EDIBLE HOUSE-LEEK.—(*Cotyledon edule*.)

THE STARRY MAGNOLIA.—(*Magnolia stellata*.)

into cultivation by Messrs. Parsons & Co., Flushing, L. I., in whose nursery they flowered several years ago, and where they received the names above mentioned. When the old firm was made into two, the stock was (presumably) divided between the new firms of Saml. B. Parsons & Sons and R. B. Parsons & Co., as we notice that both firms offer them in their catalogues. Aside from their intrinsic merits, these trees have an especial interest as being American introductions. We give an engraving from a drawing, made last spring from the original stock of the one called Hall's Magnolia. The flowers were received at one time, and the leaves at another, and by some misunderstanding, the artist has put the flower upon a leafy branch. This conveys a wrong impression. Like *M. conspicua*, *M. Soulangeana*, and other Chinese Magnolias, this produces its flowers in advance of the leaves, and to show it correctly, the flowers and leaves should be presented on different branches. The plant has a dwarf habit, and will probably not reach a height of over 6 or 8 feet. It produces a great abundance of bloom, which appears earlier than that of the two well known kinds just named. The pure white flowers are produced in such profu-

and the case of this Magnolia calls for a renewal of this protest, as it affords an example of the confusion it leads to. No conscientious botanist gives a new name to a plant unless he is well convinced that the plant itself is new. Still, with all possible care, our books are loaded with synonyms. We would not imply that the nurserymen would willingly give a name to a plant already described, but, with a few rare exceptions, nurserymen have not the books, herbaria, and other facilities for determining whether the plant new to him is really new to science. This Magnolia seemed to be new, and it was named *M. Halleana*, was sent abroad under that name, and only in June last was figured as such in "The Garden," (London.) It now appears that it is really an old plant, it having been figured 25 or more years ago by Siebold & Zuccarini as *Buergeria stellata*, as they considered it distinct from *Magnolia*. Sir Joseph Hooker, in a recent number of the "Botanical Magazine," puts the matter right by figuring it under the proper name, *Magnolia stellata*, and before this article was put in type, there came to hand the "Revue Horticole," in which the plant is figured by Carrière under the same name. *M. Halleana* must therefore be dropped.

general term "succulents," are included plants with no immediate botanical relationships, the large family *Compositæ* furnishing several, though the great majority belong to the Stone-crop Family (*Crassulaceæ*), of which the old and well-known "House-leek" (*Sempervivum tectorum*) and the common "Live-forever" (*Sedum Telephium*), now in some places only too common as a weed, are the most familiar representatives. The majority of the "succulents" being tender, mosaic bedding can only be undertaken by those who have sufficient greenhouse room for the storing of the plants during winter, and examples of this style of gardening are limited to the grounds of those with proper means and facilities. The plants most largely used are the different species and varieties of what are given in the catalogues as *Echeveria*, and comprises plants from almost every part of the world, including several, and those among the most striking, from our Pacific Coast. But botanists (Hooker & Bentham abroad, and Gray, Watson, and others at home,) have lately found that there is no good reason for the existence of the genus *Echeveria*, as distinct from the older *Cotyledon* of Linnæus. So the plants named in

honor of one *Echeveri*, who drew Mexican flowers so handsomely, must go back to *Cotyledon*, so named from the Greek word for a cavity or cup, the foliage forming a sort of leafy cup. Long before mosaic planting in our gardens with *Cotyledons* (or *Echeverias*), and similar things, was thought of, the writer had a view of a most complete and extensive example of mosaic work, which was perfect in its way, it being nature's own planning. In 1852, we made an excursion to the Coronados Islands, a rocky group rising abruptly out of the Pacific, some 30 miles directly west of the beautiful harbor of San Diego. It was a difficult matter to make a landing, and an equally difficult one to scramble to the top of the rocky cliffs. At the top were a few acres of rock, seamed and creviced in every direction, and wherever there was a seam that would give the plants a foothold, there grew, as thickly as they could stand, what we may call the "Powdered House-leek," *Cotyledon pulverulentum*, now one of the most esteemed and most effective of the succulents employed in mosaic bedding. The species is called *pulverulentum*, because the leaves, which form a beautiful rosette, appear as if sprinkled with some white powder; there were besides this, less numbers of one or two other species. The formal shape of these plants, each being an almost exact duplicate of its neighbor, their regular disposal in the long lines of crevices, and the fact that they made up nearly the sole vegetation of the surface of these islands, formed a scene most weird and striking. The surroundings contributed to the strangeness of the picture. It was framed in by an immensity of ocean, the dash of which against the rocks made a solemn diapason, relieved only by the shrill cries of the sea-lions disturbed by our arrival, and the screams of multitudes of sea-fowls unaccustomed to the presence of man. As we looked upon this example of nature's mosaic planting, we little thought that we should thereafter see the same plants contributing to the attractions of the gardens of Mr. Hume at Wellesley, or of Professor Sargent of Brookline, both in far off Massachusetts. With this personal digression we come back to our succulents, the *Cotyledons*. Among the species on the Pacific Coast, one appears to have escaped the attention of cultivators, *Cotyledon edule*, which may be called the "Edible House-leek." Since seeing it wild on the Pacific Coast, we first met with it in cultivation in a small but choice collection exhibited at the Centennial by Miller & Sievers, of San Francisco, Cal. Since then we have received it from a California correspondent, and this summer have had it in flower. The plant forms a tuft, a foot or so across, made up of numerous short leafy branches, one of which is shown in the engraving. The leaves, it will be seen, are cylindrical, and are from three to five inches long; they have a peculiar glaucous hue—a very pale green—and would be quite as useful in producing planting effects as the *Kleinia*, now so much employed. The flower stems are a foot or more high, and produce a panicle of whitish flowers, like those shown in the engraving reduced in size. This is very unlike in its general aspect to any other species of the genus, and its horticultural value as a bedding plant has not yet been fully tested. At all events, we find it an interesting plant for a cool green-house, and value it none the less because it is a native. It was described by Nuttall, who first made it known, as *Sedum edule*; the specific name was given because the Indians of the Coast used the young leaves as food. As these Indians eat everything from acorns to grasshoppers, we can not, upon their evidence that it is edible, add this to our list of garden vegetables.

Keeping Celery in Winter.

BY PETER HENDERSON.

[Last winter was so mild over a large portion of the country that great difficulty was found in keeping celery, and the losses were often heavy. Though written last January, this article is of more use now, when growers of celery are thinking as to the methods of storing their crops. One would suppose that so simple a rule as "govern the amount of covering

by the temperature," would be observed by every one. But experience last winter showed that it was not, and it seems to be necessary to repeat the simplest directions year after year.—Ed.]

A correspondent from Harrisburg, Pa., writes me under date of December 24th, as follows: "I have followed your instructions, given in 'Gardening for Profit,' of how to preserve celery in winter, for the past four years, and never failed until this season. Can you tell me why it is that my celery is rotting? Please reply in the *American Agriculturist*, as the answer may then benefit others as well."—Yes; the reason is easily explained. In almost every section of the country the season has been unusually mild—warm, in fact—consequently if you covered up your celery in the trenches, at the usual time of covering, nothing could prevent it beginning to first make roots prematurely, then to blanch or become white, and eventually to rot. In this vicinity (Jersey City Heights) we have scores of old celery growers, some of them growing half a million roots annually, and quite a number of them blundered just as the Harrisburg man did. The consequence was that the New York market last year was flooded with celery from the middle of December to the middle of January, so that instead of selling at the usual and paying price of 3c. per root, it has not averaged 1c. per root for all sold between these dates, to say nothing of probably one-third of it having rotted entirely. Now there was no occasion whatever for this loss, for there was no necessity to place any covering whatever on celery in trenches in this district, until the 28th day of December.

We grew some 10,000 roots ourselves from which to raise seed, but allowed it to remain uncovered until that date, and it is now nearly as green as when it was put away. By taking the precaution to have the covering placed along side of the trenches in heaps, ready to throw on on the approach of a cold snap, all danger of being caught by frost can be avoided, for a cold snap never comes so suddenly but that there is time enough to cover up before harm is done. In this matter, as in many others in gardening operations, the most successful cultivator is the one who does not follow blindly any given directions, but who will exercise his common sense when the exigencies of climate or any thing else require him to deviate from the beaten track of the usual practice.

Winter Bouquets, Grasses, etc.

As usual, at this season, we have inquiries as to the preparation of grasses, flowers, etc., to use for winter decorations. In 1874, we published a series of articles on this subject in which were given the results of our own experience, with such information as could be gathered from trustworthy sources. Those who have the volume for that year will find in the several numbers for August, September, October, and December, an article in which these matters are treated in full. It is not practicable for us to go over the whole ground again, in the same detail, but for the benefit of new readers, we give the principal points, referring those who wish for further particulars, to the articles in 1874. In Europe, the preservation of flowers is a regular business carried on in large establishments and employing many hands. Great numbers of these flowers are imported by our dealers, both made up in wreaths, bouquets, baskets, etc., and in bunches or clusters all of one kind. Most of the made-up affairs are not of a kind that appeal to our taste, the object being, apparently, to crowd the greatest possible variety of the most positive colors—even to black (!) in each design. The effect, as a general thing, is artificial and tawdry.

As to Grasses.

These are largely imported, and of late years some dealers have offered many of those collected in various parts of this country. These for the most part are dyed of various brilliant colors, and look to our taste, so thoroughly unnatural, that we are repelled rather than attracted by them. The pleasing effect of grasses is in form, rather than in color,

and when we see specimens which are naturally of a soft green or straw color, dyed with the most intense crimson or blue, or of a green, the like of which no grass ever presented, the eye is arrested by the "stunning" color, and takes no note of the beauty of form. Others load their grasses with crystals of alum; and worse yet, others are given a metallic appearance by the application of bronze powders. We can describe how these things are done, but we can not find beauty in them.

The Time for Collecting Grasses.

Each month there will be some grasses in season, and though many of the earlier ones have gone by, there will be found, during this month and next, a sufficient variety, especially of the larger kinds. As some of the most pleasing kinds are of no agricultural value, they are not generally known by common names, and to give their botanical names would be of no use except to botanists, who do not need them. We therefore simply say, that by road-sides, in meadows, and especially in moist and swampy land, grasses are to be sought for. Not only the more showy kinds, but those which have delicate, fine panicles or flower clusters should be collected. Secure long stems, and cut away the leaves. In most grasses the upper joint that bears the flower cluster will pull out readily from the sheathing leaf; this will often leave the stem too short to make up conveniently, and it is better to take several joints of the stem and cut away the leaves. If one can choose the time for collecting, the grasses should be watched as they develop, and taken when in flower, which may be known by the protrusion of the *anthers* or the feathery *stigmas*. Some grasses if gathered much later than this, will drop portions of their flowers, or shed their seeds in an unpleasant manner. Still, if one is but temporarily at a locality, a desirable grass should be taken in the condition it is found at the time.

Drying the Grasses.

Those in which the panicle is graceful and drooping, should be dried so as to preserve the natural form. If such are tied in bunches and hung up carelessly, they will be disappointing when dry. A handy method is to have a broad and not very deep box of sand, and stick the stems in this. Those kinds in which the flowers are in a close and spike-like cluster, may be tied in convenient bunches and hung up, heads down; a little practice will teach the proper treatment if it be remembered that the form in which the grass is dried can not be afterwards changed. Any airy place will answer for drying, such as an unoccupied room, or an old-fashioned garret. When the stems are quite dry, the flower cluster will be so; and if the drying place is not quite free from dust, they should be put away from dust and from flies, which are very fond of collecting upon them.

Besides the True Grasses

there are various members of the Sedge Family that are worth collecting, especially the Cotton-grasses (*Eriophorum*), which show their white and brownish plumes in the boggy meadows. Indeed, whatever plants by grace or beauty of form commend themselves to the collector, should be gathered, without reference to botanical relationships.

Preserving Showy Flowers.

While grasses are as much flowers as roses and camellias, they are not popularly so regarded, and in the trade, "preserved flowers and grasses" are offered. We compromise the matter by calling the others "showy" flowers, of which a large number are prepared abroad. The class of annuals known as "Everlastings," are cultivated by many with a view to the use of their flowers in winter decorations. The majority of these require only to be picked as they just come into bloom, carefully dried and kept from the light and dust until wanted. A large number of the imported flowers are preserved by means of sulphur fumes, the process being precisely that used in bleaching straw hats. A box or barrel is provided, which, if not tight, may be made so by pasting paper over the joints; this should have a small opening near the bottom to admit air, which can be closed when needed; a few inch and a half holes to be stopped

with plugs will answer. An arrangement should be made to support crosswise sticks at the top; a tight fitting cover and an old iron pan, or flower-pot with the hole plugged, to hold live coals, complete the outfit. The flowers are tied in small clusters in such a manner that the fumes can reach all parts, and hung upon the cross-sticks, live coals being put in the pot or pan, a few lumps of sulphur are thrown upon them and the cover placed on; if the cover does not fit closely, put folds of wetted cloth under it and a heavy weight on top. When the box or barrel is well filled with fumes, close the lower air hole and leave all untouched for 24 hours. At the end of this time, remove the flowers and hang them in an airy room to dry. When quite dry they may be laid away in boxes. All flowers do not succeed equally well, and there is room for experiment. Among those we found most satisfactory were, China Asters, Fuchsia buds, Larkspurs—the dark colored kinds, Red flowered Spiræas, Golden-roses, Roses—the red well filled and not over-blown ones answering best. As a general thing, the flowers are better if taken just as they are opening; some, such as the Fuchsias, even in the bud, to be opened afterwards. Some flowers after sulphuring will be quite bleached, others will have the color heightened; but the color in most can be restored, as we may show in speaking of making them up.

Village Improvement.

Some Important Suggestions to Beginners.

Mr. Canning, the author of the article on this subject in the August *American Agriculturist*, and Secretary of the Laurel Hill Association, makes the following additional suggestions for the guidance of those who are about to combine for the purpose of Village Improvement—suggestions which his experience has found to be of primary importance:

1. Have available funds at command before striking a blow—funds sufficient to accomplish something noticeable before the community.

2. In order to preclude the inevitable consequences of a mere spirit of ardor, the decline of interest as it becomes an old story, and to secure permanence to your organization, arrange for a subscription of a fixed sum for three years, at least—longer, if possible. The extent of your operations can then be intelligently forecast and accomplished.

3. By all means have the ladies of the place engaged in the plan at the outset, and give them full representation upon the Executive Committee.

4. Don't undertake too much at the start. Operations were better confined to some greatly needed betterment, and success there, will, as in case of a partially constructed rail-road, prompt to continuance in the same line.

5. Hold the meetings of the Executive Committee, regularly, as often as monthly, and from house to house, during the working campaign. The important element of *sociability* will thus be incorporated, and tend materially to activity and success.

6. Let each particular department of work be placed in the hands of a sub-committee, with an efficient chair-man or woman, who shall, at each meeting, report its proceedings since the last.

7. Have all labor accounts examined by a competent officer, and all drafts upon the Treasury countersigned by the president or other authority.

8. For obvious reasons, have your Association chartered under State law.

The Red Cedar from Seed.—The seeds of Red Cedar rarely germinate until they have lain in the ground for a year. Instead of sowing such seeds and keeping a large surface clear of weeds for one season, nurserymen resort to what is called "stratification." The seeds are made into a heap, with alternate layers of earth, and the whole covered with several inches of soil; or the seeds may be mixed with earth in a box with holes in the bottom, which is to be plunged in the soil up to its edges. In either case the seeds will be subjected to the same alternations of temperature and mois-

ture that they would experience if sown. The next spring, the seeds, if large, may be separated from the earth by a sieve, or if small, earth and seeds together may be sown. Like most other seedling evergreens, the Red Cedar needs shading while young.

THE HOUSEHOLD.

For other Household Items see "Basket" pages.

Common Weeds Made Ornamental.

Last fall we saw in a New York seed-store among dried and colored grasses, and other materials for winter bouquets, a box of curious balls of down, each about two inches in diameter. The dealer did not know what they were, and as they were too delicate to allow of thorough examination, the only clue to their real nature was the bit of dried stem attached; and from this we guessed they were in some manner prepared from thistles. Walking with a lady in the country this summer, we jocularly proposed to add a thistle to the flowers she was gathering. "But do you know," said she, "what a pretty ornament can he made from the thistle?"—Then the mystery of the puzzling balls was solved. The large common Thistle is best for the purpose, and the manner of treating it may be shown by a rough drawing. The thistle deprived of its armed leaves as in figure 1, has a green prickly cup, *a*, and the showy or colored portion, *b*, which really consists of a multitude of separate little flowers, or florets, each complete in itself; these are attached to the bottom of the green cup, and are held together very closely by its upper edge. The bottom of this cup on which all these flowers stand, the botanists call a *receptacle*, and in the thistle it not only receives all these little flowers, but mingled among them a vast number of pure white delicate hairs, which are too soft to deserve the botanists name of "bristles." It is these hairs or bristles that make the ornament in question. To get at these, first cut away the leafy cup a little below the middle, about at the point, *a*. This will require some care, and a sharp knife or small scissors. It will be found that this cup, or "involucre," is not a solid piece, but is composed of numerous leafy scales, closely overlapping one another, and most of these scales are each tipped with a sharp prickle, as careless handling will soon demonstrate. All the green scales of the upper half of the cup being carefully removed, and some of the innermost are very delicate, then commence to pull out the purple florets a few at a time. As each of these has very fine hairs attached to it, do not think that the wrong material is being removed; if the florets are taken by the tips and pulled gently they will come out all right. Slow progress will be made at first, as the number of these little flowers is something astonishing. When the last floret is pulled out, the thistle will appear as in figure 2, with the remains of the cup, *a*, and a dense brush, or short

Fig. 1.—THISTLE HEAD.

Fig. 2.—PREPARED THISTLE HEAD.

plume of the white silky hairs of the receptacle. But this is by no means a ball of down. For that, we must trust to nature, for art has done all it can towards it. Hang the thistle head prepared, as in figure 2, in the sun, and the rest will do itself. These thistle balls may be kept suspended or put away in such a manner that they will not lose their shape, until wanted for winter bouquets or other decoration. We perhaps should not have given so much space to describing this, did it not at the same time give an instructive lesson in the structure of the thistle head, and through that a general idea of the arrangement of the flower heads in the great Composite Family of plants to which the Thistle belongs, in which the same plan or idea is worked out in their structure in wonderful variety.

The Common Ox-eye Daisy, or White Weed,

that pest of the farmer, who ever supposed that anything interesting or amusing could come of that? The lady referred to (an artist in many ways), as another lady saw the possibilities of a beautiful head in a lump of butter, saw in this commonest of weeds a possible head, which is here represented in figure 3, that its beauty may be manifest. In the Ox-eye Daisy we have another composite, its green-cup, small and flat, and two kinds of florets, the

Fig. 3.—FOR THE BUTTON-HOLE.

yellow disk and the white ray flowers. Removing some of the ray florets altogether, clipping the others to form the cap border, or *halo*, leaving two in proper positions for the strings; it only needs the features to be put in with pen and ink, to show how art can improve upon nature. With a bit of green this makes a button-hole bouquet quite unlike any in Miss Hassard's work on floral decorations, and the prepared flower heads, may be preserved for use in winter at fairs and otherwise.

BY FAITH ROCHESTER.

Our Children and the Wicked World.

A little boy of five years is shut away from the wicked world by the loving care of parents and friends, in order that he may grow up free from the faults and vices that infest society—a model of all the virtues. It is proposed that he shall receive his education entirely by private instruction, until he goes away to college. No playmates are allowed him except such as are approved by his parents—"good" children, of course. I do not know exactly how this plan will work, but I feel sorry for the child, and sorry for his parents. I am afraid they believe in the "white paper" theory—that each babe is like a sheet of pure white paper upon which the parents may write just what they please, so that his character at maturity may give the exact impress of their efforts to train him. Now, I have never had any of this "white paper" to deal with. Neither have I ever seen any. I have seen children who were certainly negative enough to rank as blank paper. It might seem that you could do almost anything with them, for you could easily "twist them around your finger," so to speak; but you could never make anything really good or great of such children. It is my belief that, instead of coming into the world mere blanks or sponges, these children are all heirs of Human Nature, with its untold capacities for both good and evil. I have never seen two alike, even in the same family. The natural dispositions are various, and different temptations affect them variously. It is, indeed, a wicked world into which they have come; but it is the world in which they must live and do their work as men and women. It is a very important part of their education that they should learn the ways of the world—not that they may practice all its arts, but that they may have some idea of what

they have to deal with, and be prepared to judge wisely in practical affairs. William's father would not let him go to the menagerie for \$100. Allen's father lets Allen go to every one that comes along. Indeed he quits work and goes himself every time. Neither father seems to know how to make the best use of that institution called "the menagerie." I suppose every boy who sees the gorgeous pictures on the walls about town, and sees and hears the triumphant procession of the incoming show, has a strong desire to go inside the big tent, and see the wonderful performances there. Why shouldn't he go? I suppose such shows have some objectionable features, but not so many or so striking, I am told, as they had ten or twenty years ago. There are certainly some educational features, not easily obtained in all parts of the country, as there is always an exhibit, more or less complete, of strange and foreign animals. I can imagine a wise father sympathizing with his children's pleasure over the glowing pictures, encouraging their curiosity about the animals by bits of zoological information, and explaining how horses are trained, and what use or what foolishness there may be in the skill of the circus rider and his horse. I can imagine him promising the little ones that he will take them to a menagerie when they are old enough, and explaining to them how wearisome and comparatively unprofitable it would be for them to go before they are old enough to see the show without undue fatigue, or to remember the different animals distinctly after seeing them. The children of such a father wait patiently for their time to come, as they see their father quietly going about his business in spite of the excitement, and in the meantime they have more rational amusements.

How to Gain Strength.

I am deeply interested in the efforts of some of my acquaintances to gain strength, and become healthy women—all the more interested because I have lately had to make some particular effort in that direction myself, being unusually wearied by a hard winter's work. How we shall all come out I can not say yet, but I am firm in the belief that my way is the best way. They all have doctors, and I have none. I confess I wanted one very much indeed to give me good advice, but I couldn't afford to put myself under a doctor's care; and I knew very well, too, what a good doctor ought to say to me, and I couldn't afford to follow his entire prescription, which would be largely of rest and freedom from care. One of my friends pays her doctor by the mouth for treating her. *He has never seen her*, but she has told him by letter her symptoms, and he sends her medicines, and gives her advice by letter. The disease which he tells her that she has is supposed to be the result of improper medicine in the first place, but the dear woman takes the medicines of the new, strange doctor, in undoubting confidence, and thinks she could not live without them. There is too much of this "blind leading the blind." My sick friends who are troubled with so much general weakness and "all-gone"-ness, are obliged to add to their tea and coffee stimulants, beer and wine, one or both, as invigorators; and yet they don't get strong. I seemed to be breaking down, too—have been walking along close on the brink of it, with what caution I could, for a long time past. I was afraid any common sort of doctor would want to go to toning me up with medicine, and I never would take his stuff, for nothing was the matter with any part of me except tired-outness. A doctor of good sense ought to tell me to rest, and I have gone into that business as well as I am able. As little hard work and care as possible, all the quiet out-door life I can get, plain, nourishing food, with a good proportion of ripe fruit—that is my own prescription, and with the help of a good, kind girl, and the kind consideration of friends, I expect to pull through. No doubt some things are more strengthening than others when put into the human stomach as food or as medicine, but I have no faith in anything which professes and really *appears* to give strength without imparting any real nourishment to the system, which simply makes a person feel strong as a re-

sult of taking it, with a reaction of weakness after the effect of the stimulant is spent, until the dose is repeated and gradually increased as the system grows accustomed to the artificial stimulation. No doubt medicine may act as a corrective of a bad state of the system, impure blood, or a clogged liver. But you can get your blood purified, and your liver unclogged, without resorting to medicine, if you choose, simply by ceasing to do evil, and learning to do well physically. Make your blood of wholesome, nourishing, well-prepared food—the most healthful meats, the best of grains, the freshest vegetables; and for drink depend as much as possible upon juicy, ripe, unspoiled fruit, with pure water when needed. Purify the blood so made by full breaths of clean, fresh air, taken into the lungs where the blood is constantly passing for such purification. Keep the blood in healthy activity of circulation by judicious exercise, both in the way of useful work and in jolly games, and give yourself plenty of sleep in the purest air you can obtain. Living in this way, you can afford to "throw physic to the dogs," and you will find it the cheapest way in the end, as all good doctors will tell you.

Cleansing Laces.

Just what kind and degree of culture is necessary to make one scorn the use of any lace except that which is known as "real," I can not exactly say, nor have I any wish to reach that high degree of social culture. The finest hand-made lace is a rare product of human skill and patience, but I have read that the very rarest and richest in fineness and delicacy, and fullness of design, is made in damp unwholesome cellars, by women who wear out their lives in the sickening business. It can not be made in dry, fresh air, moisture being a necessary factor in its production. Slowly, painfully, the beautiful pattern is wrought, stitch by stitch, of the finest material, and of the bodies and souls of our sister women. You and I can do without it, and let fewer life drops fall in consequence. Indeed we must do without it, most of us, it is so exceedingly costly, and I hope we neither envy those who are able to wear it, nor feel like crying "sour grapes" about it.

But real Valenciennes and thread lace sometimes come within the purse range of people who can afford to read the papers. It is poor economy and poor taste to wash and iron these like common rags. A much better method seems coming into common use, and nearly all laces good enough to wear at all, should be washed in this way. This includes lace and tatting collars, pieces of footings, and also the better kinds of machine-made lace.

Take a large-sized bottle—a common junk bottle will do—and wind it smoothly with several thicknesses of white cotton, or at least two thicknesses of clean white flannel. Fasten this smoothly. Begin at the lower end of the bottle and wind the lace around it, the scalloped edge down, bringing it around so that the edge of each row just overlaps the straight edge of the preceding row. With a fine thread baste the lace in position, pulling it out evenly, and snug, but not stretched, over the flannel. Over this wind carefully two thicknesses more of white flannel or stout cotton cloth, sewing it snug. Put this into a kettle and cover it with soft water, in which sufficient soap of the best quality—White Castile, if you can get it—has been shaved to make a good suds. To this add a small half teaspoonful of borax, or a few drops of aqua ammonia. Let it come to a boil, and continue boiling only a few minutes. Set off the kettle, and remove the bottle when the water is cool enough to allow pressing out the suds gently with the hands. To rinse and starch the lace—put the bottle into a kettle of clean water, stirring in a few drops of bluing and stiffening of some kind. Rice flour starch is said to be the best, but well made common laundry starch is used, and simple gum-arabic water is recommended. When this water boils, take the kettle again from the fire and partially cool the water by standing. Press out all the moisture possible, then hang the bottle in the sunshine until its wrappings are dry. Rip off the outer flannel and remove the lace. If the edge does

not look even and new, pick out the pearly with a pin. Of course the lace should not be ironed.

This involves some trouble, but if one wears nice laces, it is worth while to take care of them. If they are laid away after every wearing in a mixture of powdered pearl starch and magnesia, they will seldom need washing. For common use and children's wear, thin muslin ruffles and pleated footings are serviceable. I buy the footings, all pleated and doubled so as to make a double ruffle, at ten cents a yard. Washed and starched with the fine clothes, and ironed without unpleating, it makes a full double ruffle with a straight edge, and is as little trouble and as cheap and pretty as anything for children's common use.

House Decorations.

A sister who inclines to help me bear my burdens, says in a late letter: "Do you ever write of house decorations?" Very little indeed, I might reply. I have no time to make the pretty little ornaments, and not much taste for many that I see in other people's houses.

I shook hands with Thoreau (in spirit), many years ago, when I read his "Walden." He wondered how people could clutter up their houses with so many things which must be dusted and taken care of daily or become a nuisance—with collections of things which are beautiful in their place—but mere rubbish in our houses.

Still, I do know that little touches here and there, brighten up a room and make it cheerful and homelike, instead of bare and barny, and each homemaker must judge for herself what she can afford, and what best use of her time she can make.

Sister, writes: "I have seen some very pretty and inexpensive lambrequins for brackets or shelves, made of scarlet or navy-blue opera flannel, or ladies' cloth, on which are sewed figures cut from lace curtain material. A yard of curtain material contains enough to go a great ways, and some of it has very pretty figures of ferns, etc., which can be arranged to suit the taste. Across the room, this looks like bead-work, and it requires very little time and labor. The edge may be pinked or bound with thin, white muslin."

"Persian rugs are quite in fashion, and very pretty. The ladies use remnants of Brussels' carpeting, cut in strips about a finger and a half wide, and then ravelled. Then they knit strips about a finger wide, garter-stitch, with strong twine, knitting in, in loops, the ravelled Brussels' yarn, shading it to suit themselves. These rugs are very durable but at the same time they are slow to make."

The Management of the Washing.

BY "CERES," HOWARD CO., MD

I confess to a little surprise that "Faith Rochester," who evidently brings so much thought to bear upon everything connected with domestic economy, has not yet, as indicated by her article in May last, come to repudiate all washing fluids, chemical soaps, and the like. In this respect, at least, I am in advance of her, having tried many of them, and being in turn an advocate for most of them, until disgusted with each. I have come back to first principles: *pure* soap and good management in the use of it. I am satisfied that when chemical preparations are used, in soaps or otherwise, the clothing will not last nearly so long, and will not retain a good color or smell without special care. I have, until lately, allowed my wash-women to take their accustomed course, which usually is very similar to that described in the article above referred to, not, however, forgetting my own early lessons, which often led me to put my nose into the middle of a basket of clothes just from the clothes line, to ascertain whether they smelled as sweetly as they used to "at my mother's." The verdict was invariably against them, however nicely they looked. A new wash-woman, and one not past the teachable age, led me to try whether my mother's practice would work as well in these days, and the result is so satisfactory I am tempted to give it to the "American Agriculturist family."

The clothing for the week's washing being duly

assorted, it is well to place coarse and badly soiled articles by themselves in warm suds, to soak until you are ready for them. Then take the colored clothes, wash, rinse, and starch, and hang them out to dry; flannels, also, should be disposed of in the early part of the day. These done, proceed to the white clothes. A little soaking in as warm suds as can be conveniently managed, is undoubtedly a help, and with that and the washing through two good suds, kept as clean by removing as your supply of water will admit of, brings them ready for scalding (not boiling.) One should never have less than three tubs to use in a family washing, and four are better. Into the deepest tub you have, throw the garments as they are washed from the second suds, shaking them loosely, and rubbing a little soap when there is any indication of its being needed. When the tub is nearly full, or you have all the clothing of that class in, pour over it boiling water in which a little soap has been dissolved, until they are well covered with the water; then cover the tub with a blanket, or whatever will hold the steam, until you can bear the hand in to wash the clothes out of this water. As this is the last of the washing, every part should be carefully examined and have whatever rubbing may be necessary; wring lightly, as the suds helps the bleaching, and spread on the grass, where the sun will fall on them the rest of the day, and keep them wet by an occasional sprinkling from a garden watering pot. This scalding has to be repeated if you have more than one tubful of clothes. With the coarsest and most soiled articles, there is no objection to boiling for a few moments, but I would advise taking from the boiling water into fresh, clean suds, before putting out on the grass. This part of the washing can be accomplished, and everything cleared up, by one or two o'clock, where there is a good, large wash. As the clothes should be left out to bleach all the afternoon, this part of the day can be utilized, if you are hiring by the day, in having the calicoes ironed. As late as you can conveniently do so, have the clothes taken from the grass, still keeping the coarse and fine ones separated, and put to soak in a liberal supply of clear water. The next morning, have them rinsed from this water, or one slightly blued after it. If dried under favorable circumstances, they will look so white and smell so delightfully pure and fresh, it will be a pleasure to wear them, and you will have the comfort of knowing your clothes wear out, instead of washing out—a much slower but more satisfactory process.

Household Notes and Queries.

"PARKER HOUSE ROLLS."—These very light, delicious rolls, which are generally obtained in perfection from the bread-bakers only, we recently found home-made, equal to the best, at Mrs. L. J. Post's "Maplewood Mansion," Ellenville, N. Y. The recipe was solicited and tried at home with good success. Here it is: Sift 4 quarts of good flour; take 1 quart warm milk, and melt in it 1 teacupful of butter, and add 2 tablespoonfuls of white sugar, a teaspoonful of salt, $\frac{1}{4}$ teacupful of baker's yeast, or its equivalent yeast cake. With these and part of the flour make a soft sponge at night if wanted for breakfast, or in the morning if for tea. When the sponge is light, early in the morning, or in the afternoon, add the rest of the flour, and knead as for bread. Roll out as for tea biscuit, and cut out in round forms about 3 $\frac{1}{2}$ inches in diameter. Grease about half the surface with butter, and lop it over, not quite half way. Let them rise in a warm place half to three-fourths of an hour, and bake quickly.

THE QUEEN OF PUDDINGS AGAIN.—This time the recipe comes from New Zealand, for which we return thanks. We suggest to our friends that we are so well supplied with this recipe, that they need not be at the trouble of sending any more.

LIQUID STOVE POLISHES.—Some, at least, of these need to be used with caution, as they contain naphtha, a highly inflammable fluid, which it is dangerous to have about. A case is reported in the New York daily papers, of a death which resulted

from the "explosion" of "Boynton's Liquid Stove Polish." The explosion was probably of a mixture of the vapor of the naphtha with the air. Selling this liquid in any form, should be restricted by law. Employing it in an article to be used in families is simply wicked. Avoid all such stove polishes.

MAKING PICKLES.—The accumulation of inquiries from new readers make it necessary to repeat certain points in pickle making, each season. The inquiry generally is: "How can I make pickles like those sold in glass jars?"—To answer this and others in brief,—really good pickles can not be made by putting cucumbers, etc., directly into vinegar. Salting removes natural juices, and allows the vinegar to penetrate the cucumber throughout. Some pickles may be made from cooked vegetables without salting; and ripe peaches and other fruits are pickled without salting, using boiling vinegar. Pick the cucumbers daily, always with the stems on. Wash, if needed, and place in a barrel, sprinkling salt among them; half a bushel of best salt is required for a barrel of pickles. Place a cover weighted with stones on the pickles, and add water to reach the cover. If few cucumbers are gathered daily, it may be more convenient to put them into a jar or keg of brine made strong enough to float a potato, using a weighted cover to keep them down. About four weeks are required to thoroughly salt them, and they may be kept as much longer as desired, by care in replenishing the brine if need be. All bright green pickles are made so by copper, indirectly used by preparing them in copper cauldrons, or directly, by the intentional use of verdigris. The attractive appearance of the pickles "sold in glass jars," is due 1st to this greenening, and 2d to the use of colorless vinegar. That sold as "White Wine Vinegar," is made from whiskey or other form of alcohol; it is just as wholesome as any other, but is merely sour, without the pleasant fragrance of pure cider vinegar. Those who regard quality rather than appearance, will use cider vinegar only for their pickles. Green tomatoes, string beans, etc., are treated the same as cucumbers.

BOYS & GIRLS' COLUMNS.

The Young Microscopist's Club.

"What, more insects?" some of you perhaps will say. How can I help it? I propose to answer the questions as well as I can, sent by the members of the Club; and if nine out of ten of the inquiries are upon insects, the replies must be somewhat in proportion. A box came a few days ago, which, when opened, appeared at first sight to contain some leaves nicely packed in cotton, but as the cotton began to move and soon became rather lively, I saw that it was a specimen of

The Woolly Aphis, or Woolly Plant Louse, which is in some parts of the country unfortunately too common. If you see, especially upon young fruit trees what look like patches of white mould, or if you find a twig that appears as if some one had wound it loosely with cotton or wool, as in fig. 1, you will do well to take a specimen home and examine it with your Microscope. While the surface of the mass is of white threads, you

Fig. 1.—WOOLLY APHIS OR "AMERICAN BLIGHT."

will find by looking below the surface, a very lively lot of small insects, little blackish plant-lice, about one-tenth of an inch long; one of them is shown of the natural size in the upper part of figure 2. But the threads—almost as white, but coarser than cotton fibres and most wool—where do they come from?—That is the curious part of it. They come from the body of the insect, which seems to have the power of producing them as needed. The lower part of figure 2 shows one magnified, with the tuft of threads. You may ask

"What this Wool is for?"

It is said that it allows the insect to be carried for long distances by the winds, and one of its uses may be to

scatter it abroad, but I think its chief use is to conceal this plant louse from its enemies; it must be a sharp-eyed

Fig. 2.—APHIS.

little bird that can see anything like food in this mass of wool. It is curious to see how their instinct leads them to huddle together in masses; a single insect does not seem to have wool enough to hide him, and they seem to know that by getting together in large numbers, they can help one another, and make a more complete hiding place. So the little fellows stick their bills into the tender bark of our young trees, and suck away for a living, while they are well concealed from their enemies. "But do they not injure the trees?"—Indeed they do; on this account they are called, in England, where they are very plenty,

"The American Blight,"

which is hardly fair to this country, as the insect came to us from the Old World. They are sometimes in such numbers, so rapidly do they increase, as to destroy young orchards. They are easily killed by the use of soft-soap, brine, or whitewash, put on with a brush. The scientific name of the Woolly Aphis is *Eriosoma lanigera*. The first name is from the Greek for "woolly-body," and the other is the Latin for wool-bearing.... Another insect common in greenhouses, and sometimes found on house-plants, hides itself in a similar manner to the one just described, viz., the well known

Mealy-Bug

of the gardeners. This is often found alone in forks of the stems of greenhouse plants or on the veins of the leaves. It is not a plant-louse, but belongs to another family,—the Scale insects. This is able to cover itself with wool, which rather than hiding it makes it the more easily seen on the green surface of the plant. Like other scale insects, it fixes itself to the plant while very young, and does not move afterwards. The insect without the "meal," or wool, is, according to Doct. Packard, that shown much enlarged in fig. 3. When covered it is a shapeless tuft of down. When there are not many they may be picked from a plant with a small sharp-pointed stick, or may be touched by a small brush dipped in alcohol.... Here is an inquiry not about insects. "T. G." wishes to know if our Microscope will show all the parts of ferns, and how, in collecting, to tell a fern from a moss. No, it would take a very costly instrument to "show all the parts of ferns," but it will allow him to see all the parts that are used in studying ferns, to tell one kind of fern from another. As to telling a fern from a moss, it will be better for me in the first place to briefly answer the question,

"What is a Fern?"

as this has also been asked by several others. Our ferns generally have their stems below-ground, from which arise the leaves (often called *fronds*), and these in the majority of kinds are rolled up in the bud in a graceful shape, as if the rolling had begun at the end, so that the leaf as it is coming out is in the shape of a bishop's crozier, as in figure 4, which shows two buds. On the veins, on the underside of the leaf, or along its margin in some, you will find a great number of dots, some round, and others long, which are called *fruit-dots*, and these serve mainly to distinguish ferns from other plants. I should have stated in the first place that ferns belong to the great series of

Fig. 4.—FERN BUD.

Flowerless Plants;

they have no proper flowers and produce no proper seeds, like the common plants we are familiar with, and though these spots on the back of the leaves are called "fruit-dots," it only means that they answer the same purpose that fruit does in other plants—that is, that they are concerned in producing new plants. Figure 5 shows a bit of a

fern frond, with the fruit-dots on the under-side; each one of these dots is, when young, covered with a little shield, which, when the plant is old, is often not easily found. Under this is a cluster of curious bodies called *spore-cases*, and very pretty things they are, when you examine them with the microscope. They are usually brownish, each little case upon a stalk, and around the case a jointed band, as seen in figure 6. When the spore-case is ripe, this band straightens out, and tears the case open to let out its contents. Being a spore-case, you will have guessed that the contents are *spores*. If you shake a fern leaf over a sheet of white paper, when these spore-cases are mature, you will collect a very fine dust, the spores; these are minute grains, some of which are shown in figure 6, which is of course greatly magnified. Each one of these minute spores can

Answer the Purposes of a Seed

in producing a new plant, but it is not a real seed, as it has not, like a true seed, a little plant, or *embryo* inside of it. The manner in which it grows to produce a new plant would hardly be understood by youngsters, and you must let that go at present, as one of the things to be learned hereafter. A few of our ferns do not produce

Fig. 5.—PART OF A FERN FROND.

their spore-cases in fruit-dots on the back of the leaves, but I can not now describe these. All the leaves you will find on a fern will not bear fruit-dots, these are called "barren fronds," while the others are "fertile fronds." You will find great beauty and a wonderful variety in the forms and markings of the ferns: indeed they are so delicate and graceful that many are gathered and pressed, to be used as ornaments, and to make

Fern Pictures and Bouquets.

To collect ferns for this purpose, a portfolio with paper should be taken on your fern hunt. Old newspapers between two stiff pasteboards will answer. The reason for this is that many of the most delicate begin to wither and curl up as soon as gathered, and by the time you reach home they will be useless. By putting them in press at once, this is avoided. As most ferns contain but little moisture, if plenty of dry paper be used but little changing will be needed. You should keep the ferns under pressure until you wish to use them in making up.—I shall have to tell you a little about mosses another time.

Fig. 6.—YOUNG FROND.

Aunt Sue's Chats.

C. C. F. wants to know "what will kill the nerve of a tooth—and what will remove freckles?"—You should apply to a dentist to kill the nerve; he killed one of mine very easily. Lemon-juice and many other remedies are proposed for freckles, but I never yet met any one who had been benefited by their use. If your skin is of the freckling sort, and you go out into the sun and air, you will get freckled; even if you should get rid of one set, you would soon get another. Your

Fig. 4.—END OF SILK CASE.

best plan is to not care two cents about the matter, but to be pleasant and jolly, so as to make you and your freckles welcome wherever you may go.

MOLLIE.—A "diamond wedding" is celebrated seventy-five years after marriage. A golden wedding, fifty years; a silver wedding, twenty-five years; crystal, fifteen; tin, ten; wooden, five; and paper, one year.

MAMIE.—A very pretty "gift, for less than a dollar," is a Sewing-silk Case made of perforated card-board, ribbon, etc. Get a sheet of pretty finely perforated card, and cut from it two pieces, each of the size and shape of figs.

3 and 4, and one each, of figs. 1 and 2. If one of the large pieces contains about 120 holes the long way, and 50 holes across the width, cut the slits as directed by the number of holes in the pattern (fig. 2); otherwise you

Fig. 1.—AUNT SUE'S SEWING SILK CASE.

must be guided by your eye. When cut they are lifted up slightly, to tuck the silk-winders under. On the other large piece, work the word "SILKS;" then put the two pieces back to back and bind them all round with lute-string ribbon $\frac{1}{4}$ of an inch wide (blue or any color you prefer). Bind all the other pieces, singly, with the same ribbon, then overhand them together as in fig. 6 (next page). Some little design may be embroidered on the pointed pieces, for ornament, or a pretty little picture may be stuck on each. Sew a ribbon-string to each point. Cut, out of plain white card-board, seven winders, the shape of figure 5. Wind two or three different colored silks on each winder, and tuck them in under the "slits." Cut one or two slits in each winder (fig. 5, next page) to fasten the ends of the silk after winding. The two side pieces (fig. 3) should just meet when closed over the silk-winders. Shut these up first, then turn the end pieces over and tie them together with ribbons.

Thanks for puzzles, letters, etc., to "Boby," Louisa J. S., "Little Boy," B. D. T., Effie S., C. M. M., Willie, Birdie, Sarah J. W., John J., Dot, Amanda G. C., Moppet, and G. W. Z.

Aunt Sue's Puzzle-Box.

CLASSICAL ACROSTIC.

The initials name a hero of antiquity; and the finals a mythical king of Italy, to whom was ascribed the introduction of agriculture.

1. A son of Zeus, who, even as a baby, displayed the qualities which betokened a capacity for mercantile pursuits.
2. A monster, the upper part of whose body was that of a maiden, while the lower was that of a serpent.
3. Was usually said of animals only, but Virgil said of man.
4. Is the typical part of the name of a promontory of the Tauric Chersonese.
5. Was one of the distinguishing appellations of "Gallia" or Gaul.
6. Was a priest of Apollo.
7. Is a Latin interjection.
8. Was a celebrated gladiator, who defied Rome in vain.

J. A. B.

NUMERICAL ENIGMAS.

1. I am composed of 29 letters:
My 12, 4, 23, 2, 6, is an Indian boat.
My 1, 13, 3, 8, is a title.
My 28, 19, 26, 17, 11, 9, is a field flower.
My 10, 29, 24, 27, is a vegetable.
My 7, 16, 22, 5, is proud.
My 15, 14, 3, 21, is a girl's name.
My 25, 18, 20, 19, is a place for money.
My whole is a proverb translated from the Latin.
ALBERT AND AUGUSTA.
2. I am composed of 9 letters:
My 9, 3, 6, is a kind of fruit.
My 2, 5, 6, 1, is a kind of fruit.
My 4, 8, 7, 9, is a piece of money.
My whole we should all acquire, if possible.
IMOGEN WELD.

***** Top—is an inventor. Base—is moderately. Left side—is a countryman. Right side—to explain. First letter of top word is also first letter of left word. Last letter of top word is first letter of right word. Last letter of left word is first letter of the bottom word.
TRY AGAIN.

HIDDEN HOUSEHOLD ARTICLES.

1. Fred, is Harry ready to take a stroll?
2. Our walk was most romantic! Up hill and down dale.
3. In the afternoon we walked up and down the street.
4. Oh! Charlie is too liberal, altogether.
5. He says he doesn't care for King or Queen.
6. Does Mat owe less than Tom?
7. Please get me an extra yard for a pocket.
8. Sew the bow loosely on the side.
9. She was lovely;—nose classic, hair luxuriant, form perfect.
10. What a goose he was to veto such an excellent proposition.

CROSS-WORD.

My first is in blossom but not in leaf.
My next is in robber but not in thief,
My third is in hover but not in fly,
My fourth is in plodding but not in ply,
My fifth is in buzzing but not in hum,
My sixth is in finger but not in thumb,
My seventh is in liking but not in love,
My eighth is in pigeon but not in dove,
My ninth is in garden but not in plot,
My tenth is in drunkard but not in sot,
My eleventh is in anchor but not in stay,
My twelfth is in fodder but not in hay,
My thirteenth is in shilling but not in cent,
My fourteenth is in circus but not in tent;
My whole smooths many a pathway,
Dispers full many a fear,
It comforts many a sorrow,
And dries full many a tear.

Correspondents will save time, if they will address their letters (to Aunt Sue) to Rowayton, Fairfield Co., Conn., from July to December of this year. But please remember that AUNT SUE is not Orange Judd Co.; the latter must be addressed at 245 Broadway, N. Y. City.

Aunt Polly's Visit to the City.

BY AUNT POLLY.

Well! 'Liza Jane, I'm glad to be to hum, though I did hev a nice time, and seen a powerful lot of things. I might as well begin to the beginnin' and tell you all about it. You see goin' as I did, rather sudden, there was no one there to meet me to the station; but Lucy's folks livin' near, I didn't hev no great amount o' trouble to find 'em. When I got to the front door, I jest stopped in wonderment, for there was two winders in it of colored glass for all the world like a church, and I think it's *persumin'* to imitate the House of God in that manner. Well, the door was opened by a colored gentleman dressed up *spruce*, I can tell you, with a white necktie, and gloves, if you please, to say nothin' of a swallertailed coat. And as I told Lucy afterward, I thought it was extravagant and highfalutin' to dress him so fine, and if she wanted, I'd send her the pattern I make John Henry's clothes by, and then she could make 'em herself. Well, when I said I'd like to see Mrs. Orson, if he didn't go and hold out a waiter; and I tell you I *was* scared, for I didn't know but what he wanted money, and as he see how surprised I was, says he, "your card, ma'am." Then says I, "I ain't got no card; you can jest go up and tell 'em Aunt Polly Beacon's come."

You ought t'hev seen the room I slept in. I allow t'was purty fine, but there was some things I didn't like about it. They told me to ring the bell if I wanted anything, but I didn't see no bell, only a row o' little knobs on the wall that I darsn't touch for the world. Then the

door—why I didn't know but I should get locked in and found dead years after, like that woman they sung about down to the town hall last spring, called the "Mistletoe Bough." There was so many knobs and handles on it that I thought I never'd get out. Why can't people stick to the good old latches that everybody understands. In the mornin' they showed me over the bouse, it must have cost a sight o' money, but things were mighty queer, I tell you. In Lucy's room they had curtains instid o' doors, and pieced they was at that! Why! they thought nothin' o' puttin' two or three kinds o' stuff together. When I saw the next room I was beat, for they had nothin' but pine furniture in it, and the carpet warn't big enough for the floor. Then there was

Fig. 5.—SILK WINDER.

a little settin' room, and they didn't have no carpet at all there, only a mat laid down; and the curtains they said was very rare, and I should hope they was, for I never see sech thin stuff in all my life, and of the strips of trimmin' on 'em, there wasn't two alike. And, if you'll believe it, there was three kinds of paper on all the chamber walls; just as if they didn't hev enough, and pieced it out with another kind. The little strips around the top they called a "freeze," and the one around the bottom a "dado," a "dado!" Did you ever bear anything so

silly! I was particular 'bout rememberin' them names, for I know'd you'd be struck when you heard 'em.

The keepin' room was queer, you'd better believe, (drawin' room, they called it, and I declare to goodness, I don't see the sense of half their new fangled names). There was a three-legged plauer in it, and them "dados," and "freeze," and against the chimney was a kind of little dresser that they had full o' chiny, (vases and pitchers and sich). Some of the vases they said, too, was more valuable than silver, because they had hand painting on them; but such daubs you never saw. Why our old rooster would a done as well if you'd given him the paint. The andirons I was took by, and if uncle Obadiah hadn't promised to give us bis'n when he dies, I'd a meb-bee-brought some home with me.

I didn't see a bit of white chiny while I was there, and what they did when they had company to tea, I'm sure I don't know. I never seed Faith Rochester write about any such thing in the *American Agriculturist*.

When I was in Almira's room, I seen what I thought was a clock, and says I, "where did you get such a pretty clock?" And says they, "laws! I don't touch that, or you'll set it off; that's the burglar alarm." And I tell you what it was, I didn't hev a minnute's pence the rest o' the time I was in that bouse, thinkin' what if the thing should go off, for I was forty times as 'fraid of that as I was of the burglars; and I suggested to Lucy that settin' a tub o' water to the head of the stairs was a very good way of frightenin' burglars.

When I seen the dinin' room, I just give up; for if they didn't hev fancy plates, they called 'em "placques," or some sech name, hangin' to the wall, and the ceilin'! Well, they had some painted ceilin's that was very han'-some, but this one—why I actually believe that after they got through paperin', they just took all the pieces they had left of every kind in the house, and pasted 'em onto that dinin' room ceilin'!

By the way, how'd the last churnin' turn out; and did my receipt cure old Miss Pipkin's rheumatiz?

ance of Dr. James Strong, S. T. D., the series of lessons below were prepared in 1860-1, and used for two years, and they were published in this Journal, February, 1862, and another series was issued in December, 1862, for 1863. Two other similar series from the Old Testament were subsequently issued, viz., No. 3, Adam to Elijah, and No. 4, Elijah to Christ. Hundreds of thousands of cards or slips, with these lessons, were called for and sent all over the country. In response to a general demand, four Question or Lesson Books were issued, entitled "*Lessons for Every Sunday in the Year*," Nos. 1, 2, 3, and 4, of which many hundreds of thousands were used in the Sunday Schools of all the leading Christian Denominations. This paved the way for, and led to the present International Lessons. (The dates for the lessons as first

Fig. 6.—SEWING SILK CASE.

prepared for 1861, correspond with those of the present year, 1878). There was one advantage in this series not sufficiently provided for in the present series, we think, viz., that the children were expected to *commit to memory* an average of seven consecutive verses every week and they thus stored in the mind some 350 or more verses of the sacred text every year.

1861.	Subject.	Chapter.	Verses.
1. Jan'y 6	Angels at Bethlehem.....	Luke ii,	8 to 14

The above Lessons embrace, in order of occurrence, some leading events, parables, etc., from the birth of Christ to the end of the Acts of the Apostles—about 61 years—and give a connected view of the history of that period. The lessons are in order of time, and the first 32 are severally selected from that one of the four Gospels which gives the best account within the compass of about 7 verses.

Tall Structures—Washington's Monument.—The highest human structures now extant are, we believe, as follows:—1. Pyramid of Cheops, in Egypt (480 feet); 2. Strasburg Cathedral (474 feet); 3. St. Peter's, Rome, (458 feet); 4. St. Stephen's Cathedral, Vienna, (445 feet); 5. Salisbury Cathedral, England, (406 feet); 6. Antwerp Cathedral, Brussels, (405 feet); 7. St. Paul's Cathedral, London, (404 feet); 8. Milan Cathedral, Italy, (400 feet); 9. United States Capitol, Washington, (307½ feet). The Cologne Cathedral was planned to be 511 feet, but after over 400 year's work upon it, it is far from completion. The Washington Monument Obelisk was at first started for a height of 600 feet. It is now taken in charge, by the Government,

and is to be 485 feet high, making it the loftiest artificial structure in the world. Some are in favor of adding 30 feet more, so that should the Cologne Cathedral ever be finished, we should still have the highest structure. Five hundred feet is less than one-tenth of a mile (5,280 feet), and is but a small height compared with the mountains of one to five miles elevation.

Talking at a Distance.

There are many ways of expressing our thoughts to others. Talking is the most common, though it takes the child years to learn what modulations or changes of the human voice represent different thoughts. We note down these sounds by letters of the alphabet and combinations of them. We learn what sounds a, b, c, d, etc., stand for, and in reading we utter the sound of each letter. The deaf and dumb, instead of sounds, use motions or positions of the fingers to represent different letters. Thus, three fingers held downward mean *m*; two fingers held down stand for *n*; if held upward they stand for *u*; the little finger held up stands for *i*, and so on. The Telegraph Operator uses dots and dashes instead of letters; thus one dot (.) stands for *e*; two dots (..) for *i*; three dots (...) for *s*; a dash (—) stands for *t*; two dashes (--) for *m*; a dot and a dash (.-) for *a*; a dash and a dot (-.) for *n*, and so on. A bit of iron (moved by electricity) making short and longer "clicks" upon the ends of a magnet, stand for these dots and dashes, and the ear translates them into letters and thoughts. Ships communicate at sea by colored flags, which in different positions stand for figures, etc. These are only some of the ways... Here is one simple mode of talking at a distance, originated by one of the editors, for the young readers of the *American Agriculturist*. It requires no apparatus, will often be useful, and be good amusement. Suppose two persons are so far apart as that they can just see each other's hands and arms. They agree that if the

right hand be held straight up (fig. 1) it stands for **1**. If held straight outward, it stands for **2** (fig. 2). If the left hand be held out straight it stands for **3** (fig. 3). Now let it be understood that each letter of the alphabet has its own number, thus 1 equals *a*; 2 equals *e*; 3 equals *i*, etc. Here is an alphabet with a number for each letter:

A—1	B—21	J—111	Q—131	X—311
E—2	C—22	K—112	R—132	Z—312
I—3	D—23	L—113	S—133	AND—321
O—11	F—31	M—121	T—211	THP—322
U—12	G—32	N—122	V—212	IN—323
Y—13	H—33	P—123	W—213	

Note.—Any other figure or number can be chosen for any letter. The numbers representing the several letters can be changed as often as desired.

Now suppose James wishes to tell George in a distant field to "come to dinner." He holds right hand out twice for 22 or *c*. Dropping both hands, he next throws the right one up twice for 11, or *o*. Next right hand up for 1, right hand out for 2, and right hand up for 1, or 121, equalling *m*. Next his right hand out for 2, or *e*. Next, right hand out, and right hand up twice, for 211, making *t*; then right hand up twice for 11 or *o*. Next, right hand out, left out, for 23 or *d*; then left hand out for 3 or *i*; then right hand up and out twice for 122 or *n*; then right hand out for 2 or *e*; then right hand up, left out, right out, for 132 or *r*—drop the hands between each letter, and pause a little between the words. All this can be done and understood quicker than you can read this description. Each can have the alphabet and numbers written down. The letters most used will soon be remembered. Two can talk silently in a room by simply using a finger or a pencil held up, right, and left.—Two parties may talk miles apart, if in sight of each other, by using a handkerchief or flag on a stick instead of the hand. Army officers talk to each other from hill-tops ten miles or more apart, by using flags several feet square, and portable telescopes to see the movements of the flags clearly.

International Sunday School Lessons.

A few weeks ago Rev. Dr. Vincent stated in London, that 7,500,000 Teachers and Pupils in the United States and Canada alone, were every Sabbath Day studying the same portions of Holy Scripture. Millions more in other lands use the same lessons. It will doubtless interest the friends of this Journal to know that the present popular plan of using International Lessons originated and received its largest impulse through the *American Agriculturist*. Thirty years ago (1848) Mr. Orange Judd prepared a regular series of lessons for each quarter, and posted them conspicuously in the S. S. room. Following up the plan from year to year, with the assist-

Tim's Kit.

A big heart often lies under a rough exterior. Our older readers will remember the incident that occurred before the door of the *American Agriculturist* office, when a ragged boot-black offered a bite from his peach to a poor comrade, and seeing him take a small bite, exclaimed, "Bite bigger Billy."—The Detroit "Free Press" relates an incident that goes right to every heart. "Limping Tim" came among the "shiners" and news-

but big-hearted urchins. Did God ever make a heart which would not respond if the right chord was touched.

Our Native Water-Fowl.

Some months ago, we gave you a picture of some interesting land birds, and we now give an engraving of two of our most beautiful water-fowls, selecting those that are known in all parts of the country. While birds of different kinds have many things in common—such as

some others, dive for their food, but live upon what they can find upon the margins of the waters they visit. These Teals are among the most common of our water-fowls, and though generally called "ducks," they differ from the true ducks, not only in structure, but in habits. The most conspicuous bird in the picture, the one at the left, and reaching forward, is the male of the Blue-winged Teal, and is readily known by the white mark like a crescent in front of the eye, as well as by the blue feathers upon its wings. The female, shown just below, has the

"RIVER DUCKS."—BLUE-WINGED AND GREEN-WINGED TEALS.

boys around the P. O. and quietly said: "Boys, I want to sell my kit. Here's two brushes, a hull box of blacking, a good stout box, all for two shillin's."—"Goin' away, Tim?" asked a comrade.—"Not 'zactly, boys, but I want a quarter the awfulest kind just now."—"Goin' on a 'scurion?" asked another.—"Not to-day, but I must have a quarter," he answered.—"One of the lads passed over the change and took the kit, and Tim walked straight to the counting-room of a daily paper, put down the money, and said: "I guess I can write if you'll give me a pencil." With slow-moving fingers he wrote a death notice. It went into the paper almost as he wrote it, but you might not have seen it. He wrote:

"Died—Lital Ted—of scarlet fever; aised three yerres. Funeral to-morrer, gon up to Hevin; left won brother."

"Was it your brother?" asked the cashier.—Tim tried to brace up, but he couldn't. The big tears came up, his chin quivered, and he pointed to the notice on the counter and gasped: "I—I had to sell my kit to do it, b—but he had his arms aroun' my neck when he d—died!"

He hurried away home, but the news went to the boys, and they gathered in a group and talked. Tim had not been home an hour, before a barefooted boy left the kit on the doorstep, and in the box was a bouquet of flowers, purchased by pennies contributed by the crowd of ragged

feathers, wings, legs, bills, etc.—all made on one general plan, you will find on examining them that they are wonderfully varied, and that each is adapted to get its living in a peculiar way. When you see the wicked-looking bill, and the strong claws of a Hawk, you know that it means mischief, and that small birds must keep out of their way. If you see the long legs and long neck of the Cranes, you know that these birds must get their living by wading. So every class of birds shows in the form of its parts, the mode of life to which it is fitted. When we come to examine what are generally known as "water-fowls," the geese, the ducks, the teals, and others, we shall find them equally fitted for their particular kind of life. They are usually strong of wing, and can make long flights. When on the water they can swim, their webbed feet being especially suited to this kind of motion; then very often, such birds can dive, and get their food from the plants which grow only at the bottoms of the streams and ponds. The picture shows you two of our most beautiful water birds, the Blue-winged and Green-winged Teals, the last named being found all over the Continent, while the other has not yet been found west of the Rocky Mountains. The ornithologists—as those who study the science of birds are called—class these as "River Ducks," which do not, like

blue wings of the male, but much more of brown in her general coloring. This bird appears in the Middle and New England States in April, on its way to its breeding grounds in the far North—though it sometimes nests in New England; and it again appears in autumn, on its way to the far South, where it passes the winter. The Green-winged Teal is shown on the right of the picture, the male on the bank above, and the female in the water below. It is very common in our fresh waters in both spring and fall, and usually passes for a duck, both with sportsmen, and in the markets. Fauciers in such matters regard the flesh of this bird quite equal to that of the celebrated Canvas-back Duck; it does not confine itself to water plants, but feeds also upon such grains and berries as it finds on land. It is very easily domesticated, and the wild birds have been known to feed with tame fowls in the farmer's barn-yard, and share their corn with them. The plumage of this bird is very beautiful; its head and neck are of a fine chestnut color, with a black chin; its wings are marked with a rich green, and it is especially distinguished by a showy curved white mark, just before the bend of the wing. Besides the Teals, here represented, the English Teal is sometimes found on our Atlantic Coast, and the one called the Cinnamon Teal is found in the far Western and Southern States.

Montgomery's Imp. Rockaway Fan!

WANTED.—An energetic partner with small capital, on a sheep or general stock farm in the South. Address, **W. W. TOWNSEND, Marshallville, Macon Co., Ga.**

THE "Model Piano."

PRICE \$150 to \$200.

The "Model" is a beautiful little Upright or Cottage piano; it is manufactured from the best materials that can be procured; the workmanship is excellent, and its durability is guaranteed; it is small, light, and occupies but little room; is easily transported, and above all the "Model" is sold at about one-third the price that is usually paid for any other reliable piano. For the above reasons, it is very suitable for people of moderate means, and those living in small houses; but it is especially adapted for beginners, and on account of its low price, commands itself to every parent, because it possesses all the principal features of the finest piano, and has none of the numerous disadvantages of the cheap organ.

For full particulars write for illustrated pamphlet, and state where you saw this notice.

ORANGE JUDD COMPANY, 245 BROADWAY, NEW YORK.

containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from p. 328.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the "American Agriculturist," containing articles referred to in the "Basket" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.60 per volume.

Our Fair List, which will be found on page 355, contains some 670 names of State, County, and other fairs to be held mainly this month and next. This is very gratifying evidence of the agricultural prosperity of the country. While many of the Secretaries of Agricultural and other Societies responded to our request for direct information as to the times of holding the fairs, we do not receive so many as we should have had, and have been obliged to take the announcements, as heretofore, from papers published in various States. If the various associations would fix upon the date early in the year, and inform us as soon as this is decided upon, it would greatly facilitate us in making up this list. As to the fairs, we say go to them; do not neglect your local fair for the sake of going to or exhibiting at the State fair, but visit both, and as many more as possible.

Comprehensive Horticulture.—The Premium List of the first annual Exhibition of the Southern California Horticultural Society, to be held at Los Angeles, Oct. 14 to 19, shows that the Society is very liberal in being "open to all the World," and equally so in the range of articles admitted to a horticultural fair. It begins with vehicles, runs through boots and cooking stoves, and includes about everything usually exhibited at fairs, down to the inevitable patch-work quilt. We would not intimate that horticultural products are overlooked, but they find themselves in unusual company. We highly commend one feature in the prizes: nearly all the second prizes are a year's subscription to the "Southern California Horticulturist."

Raising Farmers—Good Help—Scarcie.—Some suggestions on these topics worth thinking of, will be found on page 335.

A Manual of Georgia, for the use of Immigrants and Capitalists, prepared under the direction of Thomas P. James, A. M., M. D., Commissioner of Agriculture. Doct. James, as Commissioner, is not only doing good work to aid those already engaged in agriculture in his State, but has put forth this compendium, which cannot fail to be of service to those who would locate in its mild climate and upon its fertile soils. This work, a generous pamphlet of 119 pages, gives, in a condensed form, a general sketch of the agricultural and other resources of the State, with statistics for each county and the principal towns. Knowing the author, we feel sure that the work is free from all exaggerations, and that its statements may be relied upon. The one fault in the work, is a failure to state how and where it may be procured, though we presume from the Commissioner himself, at Atlanta.

Physicians will be interested in the suggestions on page 334, concerning treatment of Animals, Veterinary Surgeons, and the "Results" referred to.

United States Entomological Commission.—The first Annual Report for 1877, relating to the Rocky Mountain Locust, is issued by the Department of the Interior. It forms one of the series of the Reports of the U. S. Geological Survey, and is uniform in style with those. When we say that three such Entomologists as C. V. Riley, A. S. Packard, Jr., and Cyrus Thomas, have put the results of their work into over 700 closely printed pages, which are abundantly illustrated by maps and engravings—some of the latter of great beauty—it will be admitted that the Locust has had justice done it. The work is highly creditable to the gentlemen of the Commission, and to the Government that authorized it, and we trust it will be most useful to the States ravaged by the insect. To this end we hope that it may be made accessible at cost price, to all who wish to procure it.

RULES FOR ARCHERY and LAWN TENNIS, 10c. per copy.

A Watch for the People.

Fig. 1.—FRONT VIEW, FULL SIZE.

A Most Excellent Watch, easily obtained for a Very Little Work; or for a Very Little Money.

Those who wish to obtain a really good, serviceable, reliable, and quite accurate Time-keeper, but who do not feel able to pay for one, or to pay but a small price for one, will be interested in the following:

Last spring, one of the Chief Editors of the *American Agriculturist*, having occasion to leave his Watch for cleaning, received a low-priced watch to carry in the meantime. He thought it would answer temporarily, if watched and corrected daily. To his great surprise, it ran very accurately week after week, varying from standard time less than a minute per week. The Agent of the manufacturers was hunted up, and during the summer different editors have obtained for themselves and friends a number of other watches of the same make, taking them direct from the general stock (not fixed up or selected ones), and carried them for weeks and months. **These watches have ALL given the highest satisfaction.** For example, one now carried by Mr. Judd has been compared daily with Benedict's Standard Clock for a month past, and it has scarcely varied a single second per day! This seems hardly credible, and, as a rule, can not be expected from any watch except one costing a hundred dollars or more, and thoroughly "adjusted to temperature and position." But this much is certain, the watches are such good time-keepers, that we can confidently recommend them to our friends wanting a watch of this kind.

Another important feature is, that these watches are *Stem-winders* and *Stem-setters*. No key is required for winding or moving the hands. (On depressing the little pivot near the ring, the stem moves the hands back or forward). So, after regulating, one has never to open the watch at all. Nine-tenths of all trouble with ordinary, good watches, comes from the admission of dust and moisture in opening, and especially from the fine dust that gets in from the key through the key-hole, and finds its way among the delicate works. All this is obviated in the stem-winding, stem-setting watches, and the necessity of biennial or annual, if not semi-annual, cleaning generally required is greatly lessened.

DESCRIPTION.—Fig. 1 is a front view of full size, and fig. 2, a back view with the cover lifted to show the interior works. These works are covered with glass, so that when thus opened, no dust can enter. The case is strong, looks well, is heavily plated with nickel, which is not easily distinguished from silver, yet is harder, and is not tarnished, like silver, by gasses or sulphur vapors from the skin. For looks and wear, for use in fact, these cases are preferable to coin silver. The case is strong and substantial, the face is protected by a strong, flat crystal with modern beveled edges, and the dial is neat and clear. That the works, the most important part, are well and carefully made, is proved by what they do, as stated above. The weight of the watch is $4\frac{1}{4}$ ounces.

How to Get this Watch Free.

The watches described above are sold so low, that the manufacturers cannot make sufficient wholesale discount to admit of their being offered as general Premiums, like other new articles. **BUT**, as a **SPECIAL OFFER**, for the great Fair Month (September), and **only for this Month**, the Publishers offer 300 of these Watches, as follows:

One Watch will be presented to each subscriber who shall, during the month of September, secure and forward 16 Subscribers to the American Agriculturist for one year, at the NEW subscription rate of \$1.50 a year, post-free. (For our new terms see the first page);

OR, 13 subscribers for $\frac{1}{2}$ years (October 1878 to December 1879, inclusive), at \$1.80 each, post-free;

OR, 31 Subscribers for one year, at the four-club rate of \$1.25 a year, post-free;

OR, 25 Subscribers for $\frac{1}{2}$ years (Oct. 1878 to Dec. 1879, inclusive), at \$1.55 each, post-free.

Fig. 2.—View of Works through the Glass Protector.

(Note 1.)—At least half of the above subscribers must be new ones, or those not now on our books.

(Note 2.)—Two Subscribers for 6 months, or four Subscribers for 3 months will count the same as one subscriber for a year, for the above premium.

(Note 3.)—To DISTANT SUBSCRIBERS—Though the above offer is limited to September, yet, to put all on a par, those subscribers living anywhere so distant as not to receive this notice before Sept. 10, will be allowed 20 days after this paper does arrive, in which to gather and forward names for this premium.

(Note 4.)—The subscribers need not necessarily all be at the same Post Office, but they must all be sent by the person who is to receive the Watch.

☞ This is the most liberal Premium we have ever

offered, or expect to offer. N.B.—It is special, and **only** for September, 1878, with the 20 days after the arrival of the paper to distant subscribers, above specified.

Capital Work for the Fairs.

Those wishing the above premium, will do well to take a copy of the *American Agriculturist* along to the Fairs, where they can gather many names—perhaps enough at a single Fair to secure the watch.

This Watch Supplied to Subscribers for \$10.

If any subscriber of the *American Agriculturist* may wish to purchase one of the above valuable watches, without getting it as a premium, or in addition to a premium one, the Publishers will procure and forward one on receipt of \$10. They are sold at from \$10 to \$20, according to locality, and are worth more for real service and reliability, than many watches sold at several times this price.

Mode and Cost of Delivery.—The above watches will be packed in a safe wooden box and forwarded by express—the delivery to be paid by the receiver. The expressage will probably amount to from 25 to 50 cents, according to distance, to points east of the Mississippi River, and a trifle more to more distant points.

The Hessian Fly and the Wheat Midge.

—These two pests stand on either hand of the farmer. If he sows early, the fly destroys; if he sows late, the midge infests the crop. Of the two evils the fly is the worse, and deserves the most consideration. This insect lays its eggs in August and early September upon the leaves of the young wheat. When hatched, the larva, a small white maggot, works down to the stalk near the root, where it sucks the juices, causing the leaves to become yellow, if not the death of the plant. A variety that starts freely and grows vigorously will therefore resist the fly better than another of less strong growth. And the more fertile the soil, the better the plant sustains the injury. The remedies are obvious. With the help of some active fertilizer and a vigorous variety of wheat, a late planted crop may be as far ahead when the winter comes, as the early crop not so favorably started. To sow on and after Sept. 15th seems to practically secure safety from this enemy.

Rain—How Much on an Acre.—A fall of rain one inch deep on an acre (43,560 square feet), is equal to 3,630 cubic feet; or 27,154 gallons; or 862 barrels. As water weighs 62 $\frac{1}{2}$ lbs. to the cubic foot, the one inch of rain on an acre (3,630 cubic feet), equals 226,875 lbs., or over 113 tons; and on a single square mile, 145,200,000 lbs., or 72,600 tons. As we write (Aug. 7), a telegram says 2 inches of rain, twice the above amount, fell in Providence, R. I., yesterday, in half an hour! The annual fall of rain over the United States, east of 100° longitude, varies from 32 to 56 inches. A mean fall of 44 inches would give 37,938 barrels, or about 5,000 tons of rain-water to every acre. It is much more in many places.

Twenty-Five Cent Dinners for Families of Six, by Juliet Corson, Supt. of N. Y. Cooking School, No. 35 East 17th St., N. Y., price 15 cts. Several months ago, we noticed "Fifteen Cent Dinners," by the same author, and the present work is written with the same laudable purpose—i. e., to show working-people and others how it is "possible to live upon a very moderate income." Bills of fare are given for each meal for every day in the week, the cost of each article being stated. Of course, to bring the prices within her limits, her directions for buying must be heeded, and the meals so arranged, that what is prepared for one, may sometimes serve in part for another. Even those who are not obliged to closely count their expenses, will find here hints for useful economy and methods of cooking, worthy of being tested. We are glad to see that the author gives due prominence to macaroni, a most nutritious article of food that may be cooked in various acceptable styles, and one which should be oftener found on the tables of the well-to-do, as well as of those who must study close economy.

Disease in Sheep.—In an item last month, by inadvertently dropping a word, we were made to say that "a soft loose swelling under the jaw," is known as "liver rot." It should have read, "it accompanies pleurisy, pneumonia, and the disease known as liver-rot," meaning of course that it is one of the attendant symptoms of "liver-rot," and not the disease itself.

Grasses Named.—"C. R. G.," Young Co., Tex.
 "Pungent Meadow Grass (*Eragrostis poaeoides*, var. *megastachya*), with us an annual weed in cultivated grounds and waste places. It has a strong odor, as indicated by its common name. It belongs to a genus of little or no agricultural value, and if your horses show a fondness for it, it is probably due to the fact that it is a change from their ordinary food. We should not like to confine an animal to this as its only fodder...." S. S., "Stonewall, Va. "Velvet Grass" (*Holcus lanatus*), and so unlike Orchard grass, that the seed could hardly have been sold for that by any competent seedsmen. It is of very little value, but is sometimes grown on soils too poor to raise a better grass...." J. S., "Henderson, N. C. Italian Ray Grass (*Lolium Italicum*), a valuable grass on good soils. The seeds may have been introduced in some packing case, or mixed with other seeds."

Pear Blight.—"J. C. W.," Hartford, Conn., and others. We are obliged to reply, as we have many times in the past, that the "cause" of the blight is not known. It is supposed to be due to fungi, but this has not been demonstrated. Its presence is not known or suspected, until the tree, or a part of it, is dead, hence remedies can not be applied. The preventives that have been suggested are numerous, but we do not find any two fruit growers agree as to their efficacy. All that, with our present limited knowledge, can be advised, is, to cut away the blighted portion, be it more or less, and for fear that fungi may be concerned, burn the prunings. Though pear blight is a topic discussed at pomological meetings more frequently than any other, scarcely any positive knowledge has been thus far elicited.

Prickly Comfrey again comes forward as a matter of interest. "A. W.," Essex Co., N. Y., calls it "a humbug of the worst kind," as even his horses will not eat it. While some maintain it is a failure as a fodder crop, others speak favorably of it, and we have no means of knowing what there has been in the treatment of the plant, or in the method of feeding it, to account for these wide differences of opinion. In our own experience, a row 300 feet long, it comes early and holds on late, and if our animals would only eat it, we should esteem it highly, but, in fact, neither of our cows would touch it last year or this; early this spring, our horses seemed fond of it, but refused it altogether after they had had a nip at the pasture. The pigs eat it, but where "pussley" and garden refuse are abundant, we see no inducement to cultivate Comfrey or other crops for feeding pigs. We much regret that we can give no more favorable report from our own experience. It would appear that this Comfrey meets with more favor in the South than in the North and West, as it will there yield fodder before corn can be made available.

The Fly in Wheat.—"B. H.," Hillsboro, N. J. The "fly" is not in the seed wheat. After the young wheat plants have come above the ground, the fly lays its eggs on the leaves near the surface, and these hatch in a few days into small white maggots, which crawl down to the bottom of the stalk, pierce it and suck the juices. Anything that will disturb or destroy the maggot or the fly will save the wheat. See "Hints for Work," page 324.

Lime, Salt, and Ashes, we would say to "J. A. B.," of Great Falls, N. H., will not make a good compost for sandy land. The ashes are all right, and the more used the better. Lime is seldom of any use on light soil, though often valuable for heavy land, and salt only on special crops or soils naturally fertile. If it is thought advisable to use either or all of these, there can be no advantage in mixing them; though the salt and lime may be put together to advantage for use on heavy soils, as the mixture results in beneficial chemical action.

Hoisting Wheel.—"J. G.," East Toledo, Ohio. A plan for constructing a hoisting wheel was given in the *American Agriculturist* for August, 1875.

Treatment for Garget.—"H."—We have found a mixture of 7 parts of Glycerine and 1 part of Iodide of Potassium, to be the most effective application for caked or swollen udder. Before rubbing this upon the udder, that organ should be well fomented with warm water for some time. Half an ounce of Saltpetre may be given to the cow daily, while the udder is feverish.

THE DINGEE & CONARD CO'S BEAUTIFUL EVER-BLOOMING ROSES

We deliver **STRONG POT ROSES** for Winter Bloom and Fall Planting, *safely by mail*, at all post-offices. Five Splendid Varieties, *your choice*, all labeled, for \$1; 12 for \$2; 19 for \$3; 26 for \$4; 35 for \$5; 75 for \$10; 100 for \$13. Send for our **New Guide to Rose Culture**, and choose from over 500 Finest Sorts. Our **Great Specialty** is growing and distributing Roses.

NEW PLANT.

TRITOMA MACOWANI, figured and described in A. A. for Feb. 1873.

LARGE PLANTS.....\$1.00 each.
 SMALL PLANTS.....50 each.
 \$5.00 per dozen per mail after October 1st. Order early as stock is limited.
WOOLSON & CO.,
 Dealers in Hardy Plants, Passaic, N. J.

**SPECIAL PRICE LIST FOR
MARKET GARDENERS
AND
FLORISTS.**

Sent free on application.

Peter Henderson & Co.

Seedsmen, Market Gardeners and Florists,
 35 Cortlandt St., New York.

Hardy, Herbaceous Perennial Plants.

These plants being "Hardy" require no protection. They are "Herbaceous," i. e., their stems and foliage die down each year. The roots being "Perennial," they last from year to year.

Plants of this kind are easily managed. Once planted, they may remain and bloom for years. No trouble of seed sowing. No green-house or frames required.

Selections made to suit various purposes, and to furnish a series of bloom from early spring to frost from

The Largest Collection in the Country.

Special collections made for Cemeteries, for which these plants are most suitable.

Native plants—some of which are not excelled in beauty by any exotics—a specialty.

Catalogues, giving full particulars, furnished on application to **WOOLSON & CO., Passaic, N. J.**

N. B.—Autumn is the most favorable season for setting out many of these plants.

WINTER RYE.

CLEAN AND HANDSOME SEED

Grown on newly burned land, delivered at Railroad in Boston for \$1 per bushel, bags 25 cents extra. Samples free by mail.

CHARLES W. WOLCOTT, Readville, Mass.

APPLE, "CHERRY," PEACH, AND PLUM TREES.

LARGE MAPLES, "EVERGREENS," Etc.
 At low rates. Catalogues sent free.

Address **GEO. ACHELIS, West Chester, Chester Co., Pa.**

Bone Meal.

Fine Ground, Warranted pure. Manufactured by
S. H. MORGAN, Toledo, Ohio.
 Send for Circular.

The Coming Raspberry. E. P. Roe's New Seedling

Pride OF THE HUDSON

Awarded the "First Prize" by the Boston Horticultural Society.

"LET OTHERS PRAISE THEE."

"As it now appears it is the largest, finest, and best flavored Red Raspberry that I have yet seen."—*Chas. Downing.*

"The Raspberries seem to me to deserve all that Chas. Downing says of them."—*Hon. Wm. C. Bryant.*

"The best Raspberry I have ever grown."—*Agricultural Editor N. Y. Times.*

"I still regard it as the finest Raspberry I have seen."—*Peter Henderson.*

"The plants you sent me have made a fine growth. They bore berries which were magnificent in size and appearance and of superb quality."—*J. T. Lovett, with A. Hance & Son.*

October is the best time to set out Raspberries.

"GOLD MEDAL" STRAWBERRY

PLANTS, over 40 varieties.

100,000 Forest Rose, also Crescent Seedling, Duchesse, Great American, Sharpless, &c., in large quantities. All the leading small fruits, true to name. Send for descriptive catalogue. Address,

E. P. ROE, Cornwall-on-the-Hudson, Orange Co., N. Y.

A MILLION OF CRESCENT SEEDLING

STRAWBERRY PLANTS:

Also **FOREST ROSE, SHARPLESS, Cinderella, Miner's Prolific**, etc., (at reduced rates), and all the standard sorts, both **POT-GROWN and LAYERS**, in large supply. **AN 8-page Pamphlet, 2d edition**, with reduced prices, mailed free to all.

A. HANCE & SON, Red Bank, N. J.

See illustrations of and notes on **Crescent and Forest Rose**, pages 300 and 301.

CRESCENT SEEDLING STRAWBERRIES.

Parmless Crescent Seedling stands without a rival. This is the third successive season this berry has produced fifteen thousand quarts per acre of fruit that readily sells in advance of Wilson, from two cents to eight, and always in demand. Single dozen plants sold in spring of '77, this season, has produced from one to two hundred quarts. In one case twenty-five plants produced four hundred quarts. Always be sure and get the genuine stock, as there are ten thousand spurious in circulation where there is one hundred genuine.

H. H. SMITH, West Haven, Ct.

NEW STRAWBERRY SHARPLESS.

The largest, best flavored, and most productive berry ever produced. Berry raised with ordinary culture from plants set in Sept 12th in circumference (weight 2¹/₂ oz.), and on the same fruit stem four others from the size of a hickory-nut to that of a walnut. See sworn statement and recommendations in my circular, which is free to all sending their name on a postal card. Address

J. L. DILLON, Florist, Bloomsburg, Pa.

Sharpless Strawberry.

What Ellwanger & Barry say of it:—"This variety (originating in Catawissa, Pa.) having fruited with us several seasons, we have no hesitation in recommending it as the Largest and Best Strawberry in cultivation. Send for Circular." **F. F. MERCERON, Catawissa, Pa.**

GREAT AMERICAN STRAWBERRY Plants, Potted and Common runners. Send for Circular, giving best method of culture, to **WM. L. RICHARDS, 22 Brill St., Newark, N. J.**

STRAWBERRIES. 16 inches—Largest—Best—Most Hardy and Productive. Plant this Fall and save a year. Great American, Monarch, Essex, Cumberland, Triumph, Sharpless, very large, excellent, firm, and productive. Crescent, Pioneer, Cap. Jack, and others.—**RASPBERRIES**, 3 inches, yield \$4.33 on 10 Acres. Send for Catalogues.
WM. PARRY, Cinnaminson, N. J.

I HEREBY WARN THE PUBLIC that the machine advertised by Geo. Ertel as the Economy Hay Press infringes and uses eight of my patents, and that said press was copied from my designs on the records of the Patent Office, or from my machines in the field, and that they are thus a swindle upon the public. Either the maker, seller or user are liable, and as the damage for infringing so many patents will be large, I propose to prosecute the latter as usually the most responsible party. Moreover, the damages are largely occasioned by the defective operation of such inferior machines, distortions of my patented designs; and the dirty ragged bales they put upon the market being my patented form of bale, not only prejudices my interests seriously, but also damages the entire hay interest of the country, as it will ruin the reputation of the Perpetual Press and bale, which means several dollars less per ton of hay. Formerly Western Hay was at a discount and but little called for in Eastern markets, but the Perpetual Press has opened up the markets of the entire country to the Western farmer and shipper, and the bales from these presses are now found and sell at an advance in all Eastern and Southern markets; no one questions that it is the Perpetual Press that has done all this, then why prostitute its reputation to the detriment of all concerned? The damages for infringing so many patents will be sure to cost the purchaser more than the press, and its use will be stopped. Why join in such a steal when you can purchase the same machine of me, the inventor, at the same prices, and with such improvements as to make them do good work and sustain the reputation and prices of the Perpetual Hay in the market? Parties who appropriate the inventions of others seldom origi-

nate anything themselves further than attaching some little side trap to the machine they pirate in order to get a patent on the side trap and make the public believe it is on the machine proper. Said Ertel copied the machine in question bodily, and the patents he claims are not on the machine proper but on little traps attached to a feed door and the pole of the truck, neither of which could be utilized on a perfect press, and he has no authority to use my patented press to apply his side trap. I am not a novice in presses and patents, but have had a life experience and am prepared to satisfy all interested that I am entitled to all I claim, and, having the ability to do so, shall protect my property to the interest of the public and myself. Do not regard this as a scare as I volunteer to furnish evidence to satisfy all upon application that the above is a statement of facts, and in all fairness I ask the public if I am not entitled to some consideration for my improvements and the benefit they have been to the hay interests of the country. Parties having these contraband presses will not be allowed to use them unless they settle with me, and, in addition, apply such of my improvements as are required to make them do good work, and turn out bales that will not sell at a discount, thereby damaging the sale of our patented bale in the market. Don't be swindled, but send to me for copies of my patents before purchasing any horizontal hay press. Price of presses guaranteed the best in the world, and cheaper at prices than any other as a gift or no sale, from \$150 upwards. Send for illustrated price list.

ADDRESS P. K. DEDERICK,
Albany, N. Y.

EUGENE ROCK, Glen Head, Queens Co., N. Y., inventor and manufacturer of the Improved Tether, illustrated in August number *Am. Agriculturist*. Price, \$5.95.

FARMER'S VETERINARY ADVISER.

By Prof. I. LAW, Cornell University, Ithaca, N.Y.
"The best work on the diseases of animals in the English language."—Country Gentleman.
Sent by mail from the Author for \$3.

THE "POULTRY WORLD,"

Hartford, Conn., is a success in its way, beyond precedent. Vol. 7 begins January, 1878. Order the best of poultry monthlies. It is original, fresh, and practical, always, \$1.25 a year. Only 75 cents extra gives every subscriber 12 Splendid Fowl Chromos, annually! Every poultryman should have this excellent Monthly. Now is the time to subscribe for 1878!

The new Weekly "American Poultry Yard," is also just out. \$1.50 a year (52 numbers) post paid. Or, both papers to same address \$2.00 only.

H. H. Stoddard, Hartford, Conn.

A SHEEP MAN WANTED.—I have an improved Farm of 320 acres to rent, for from 3 to 5 years, and a Flock of Sheep to let on Shares for same length of time. None but a practical Shepherd and Farmer need apply. Capital required, \$1,000 to \$1,500. The best of references given and required. Address B. J. G. Bettelheim, Brookfield, Mo.

Allen's New American Farm Book...\$2.50

Allen's American Farm Book, (the former edition of the present volume), has been one of the standard farmers' hand-books for twenty years; it is still a valuable book, but as its author, Mr. R. L. Allen, could not give time to its revision, this was undertaken by his brother, Hon. Lewis F. Allen, the distinguished farmer of Erie county, editor of the American Shorthorn Herd-Book. The present edition of the work is greatly enlarged, and full of suggestions from the rich experience of its editor and reviser, and is called the NEW AMERICAN FARM BOOK. Originally by RICHARD L. ALLEN, Revised and greatly enlarged by LEWIS F. ALLEN. Cloth, 12mo.

Swine Husbandry.....\$1.75

A most valuable Practical Manual for the Breeding, Rearing, and Management of Swine, and the Prevention and Treatment of their Diseases. While written from a Western breeder's standpoint, the usefulness of the book is by no means limited to any section of the country. It is the fullest and freshest compendium relating to Swine Breeding yet offered. By F. D. COBURN, a Western Practical Farmer and Breeder.

Harris on the Pig.....\$1.50

The points of the various English and American breeds are thoroughly discussed, and the great advantage of using thorough-bred males clearly shown. The work is equally valuable to the farmer who keeps but few pigs, and to the breeder on an extensive scale. By JOSEPH HARRIS, author of "Walks and Talks on the Farm," etc. With numerous Illustrations. Cloth, 12mo.

Either of the above books sent post-paid on receipt of price by

ORANGE JUDD CO., 245 Broadway, New York.

Also Cows and Heifers: South-Down Sheep, and Berkshire Hogs, Collie Dogs, and White Dorking Fowls.

WM. CROZIER, Northport, N. Y.

THOROUGHBRED JERSEY BULLS.

The time for breeders and dairy farmers to purchase is the present. I offer for sale 12 JERSEY BULLS, from 11 months to 26 months old. All were sired by my bulls "Pierot 3d" or "Pierot 7th." No better sires exist. All are from cows of large butter yield. All have beautiful colored coats and skins and several are solid fawn with black points. All are able to serve cows at once. Five of them are subject to entry in the A. J. C. G. Register. Of course they must be gilt-edged. Lowest price, \$100; highest price, \$200.

THOMAS FITCH, New London, Conn.

Automatic Cow-Milker.

I have the best and simplest milker in the world, made all of pure silver. It is easily kept clean, and has no flexible or rubber tubes to sour and spoil the milk in warm weather. It is easily applied, and can be seen while milking that every teat is flowing.

Will milk sore or short teats, or klicker. Fractions cows become very gentle by the use of my milker. It is the cheapest, best, and only perfect milker. It never gets out of order—never wears out. It will milk any cow very quick. Price \$3.00 per set; two sets, \$5.00. Single Tubes, 75 cents. Full directions. Agents wanted for every County in each State. WM. F. ELY, P. O. Box 226, Madison, Morris Co., N. J.

Self-Milking Apparatus.

(Trade Mark Registered in the U. S., July 30, 1873.)

This is the Original English Cow-Milker, Imported by Mr. William Crozier, of Northport, L. I., and described in the Editorial columns of the American Agriculturist for June, 1878.

The attention of Cow-keepers, Farmers, and Dairy-men is called to the NEW SELF-MILKING APPARATUS. This Apparatus or Cow-Milker, has been tested by a large number of practical Agriculturists, Dairy-men, &c.; and, without exception, merited high encomiums and commendations, for its adaptability and wonderful rapidity in the Milking of Cows. It is considered one of the most invaluable and useful Machines yet invented.

Amongst its many advantages are—

1st—It is SELF-ACTING, easy of application; and can be used by any person, however ignorant of Milking.

2nd—It will Milk any Cow in FOUR Minutes effectually, and its use is more agreeable to the Cow than Hand-Milking.

3rd—It is a great boon in the case of Sore or Corded Teats.

4th—Its Usefulness, Simplicity, Saving of Time, Cleanliness, Durability, and Cheapness, prove it to be a most important and necessary adjunct to a Dairy, and it has only to become better known to be universally used.

Sent free on receipt of Post Office Order for \$5. Printed Instructions accompany each Machine.

All infringements will be vigorously prosecuted.

MILK TUBES.

COW-KEEPERS should not be without one of these, as they are invaluable for sore or Corded Teats.

THE ART OF GRAFTING AND BUDDING.

By CHARLES BALTET.

ILLUSTRATED.

This is the most complete work on Grafting—including Budding—in any language, and though the American propagator may not need to use many of the processes here described, it is well for him to know about them. We know of no other work that is so full on this method of propagation in all its varieties.

Price, post-paid, \$1.75.

ORANGE JUDD COMPANY, 245 Broadway, N. Y.

A COPPER BULL-RING,

2½ inches in diameter, of the most approved pattern, with screw-driver for putting it together, will be sent, prepaid, on receipt of \$1.00. Address

ORANGE JUDD CO., 245 Broadway, New York.

A Trochar for Cattle-Men.

In June of 1872 we gave illustrations of a Trochar and Cannula to be used in ringing a bull, and on page 13 (January) and page 97 (March) of the American Agriculturist for 1873 (copies of which may be got from this office for 15 cents each) we described the use of this apparatus in relieving hoven in cattle. These articles have brought out a large demand for Trochars, and failing to find just the right kind among the makers of surgical implements, we have induced an establishment to undertake their manufacture. We give herewith a small engraving of the Trochar. These articles are now in the trade, and may be had of most dealers in agricultural implements. Those who can not get them from dealers can receive them from this office, prepaid, for \$1.00.

ORANGE JUDD COMPANY,
245 BROADWAY, NEW YORK.

A Sportsman's Miniature Library For \$10.

LOGOMACHY.

WAR OF WORDS.

A most useful as well as entertaining game for young and old on the construction of words. It can be played by three or more persons. Every game played is as good as a "spelling lesson" for children. Add it to your camp outfit.

PRICE, POST-PAID, 50 CENTS.

Go-bang, the unrivalled pastime, for young and old, was introduced here two years ago from India, where it has long been the favorite game of the British Army. During these two years it has

achieved great popularity in the United States. The game can be played by 3, 4, or 5 players. Four players afford the best opportunity for a display of skill. This is a fine game for camp recreation.

Handsomely mounted (folding), bound in cloth, with card-board counters.....\$1.25
Ditto, with bone counters.....2.00

Delivered free by mail or otherwise on receipt of ten cents additional.
